# The Crystal Structure of Ru,1B,

#### JAN ASELIUS

Institute of Chemistry, University of Uppsala, Uppsala, Sweden

The crystal structure of Ru<sub>11</sub>B<sub>8</sub> has been determined by single crystal methods.

The orthorhombic unit cell has the following dimensions:

a = 11.60, Å, b = 11.34, Å and c = 2.83, Å.

There are two formula units in the elementary cell and the space-group is  $Pbam - (D_{2k}^0)$  No. 55.

The twentytwo ruthenium atoms are situated in one twofold position and five fourfold positions with two ruthenium atoms in 2(a), twelve ruthenium atoms in three fourfold positions 4(g):  $x_{\rm II}=0.2844$   $y_{\rm II}=0.3913$ ,  $x_{\rm III}=0.0429$   $y_{\rm III}=0.3952$ ,  $x_{\rm IV}=0.1686$   $y_{\rm IV}=0.1740$  and eight ruthenium atoms in two fourfold positions 4(h):  $x_{\rm V}=0.4636$   $y_{\rm V}=0.2962$ .  $x_{\rm VI}=0.3404$   $y_{\rm VI}=0.0616$ .

 $y_{\rm V}=0.2962, x_{\rm VI}=0.3404 \ y_{\rm VI}=0.0616.$  The sixteen boron atoms are also situated in fourfold positions with four in 4(g):  $x_{\rm II}=0.34_{79} \ y_{\rm II}=0.21_{56}$ , and twelve in 4(h):  $x_{\rm I}=0.13_{98} \ y_{\rm I}=0.01_{81}, \ x_{\rm III}=0.15_{23} \ y_{\rm III}=0.32_{65}, \ x_{\rm IV}=0.27_{99}$ 

 $y_{IV} = 0.25_{35}$ .

Very little is known about the structures of the borides of the platinum metals.

Buddery and Welch <sup>1</sup> have prepared a number of such borides by direct combination of the elements.

Mooney and Welch <sup>2</sup> determined the crystal structure of Rh<sub>2</sub>B from single crystal data. Later Aronsson <sup>3</sup> determined the crystal structures of Ru<sub>7</sub>B<sub>3</sub> and Rh<sub>7</sub>B<sub>3</sub> and Aronsson and co-workers <sup>4</sup> the crystal structures of RhB, PtB and IrB<sub>1.0</sub>.

The present paper gives an account of the crystal structure of the phase  $Ru_{11}B_8$ .

#### EXPERIMENTAL

Alloys were prepared by high frequency-melting ruthenium (claimed purity ca. 99.8 %, obtained from Heraeus, Hanau, Germany) and boron (claimed purity 99.0—99.7 %, kindly donated by Borax Consolidated, London). No chemical analyses were carried out and all compositions reported are nominal.

The reaction products were investigated with X-ray powder methods. Guinier-type cameras with CuKa-radiation were used. The unit cell dimensions were determined with

 $CaF_{a}$  as internal calibration standard, a = 5.4630 Å.

For the single-crystal work, a small, roughly spherical crystal fragment was selected from a crushed Ru<sub>1.25</sub>B-alloy. Single crystal photographs were taken around the c-axis with an equi-inclination Weissenberg camera with niobium-filtered MoK radiation. The multiple film technique was employed with thin iron foil between successive films. The intensities were visually estimated with the aid of a standard intensity scale. The summation of the Fourier series and the structure factor calculations were made on the electronic digital computer BESK with programs (available at BESK) devised by M. Edstrand and Asbrink et al. In the structure factor calculations the atomic scattering factors were approximated to the following expression:

$$f_{i} = A_{i} \exp \left(-a_{i}/\lambda^{2} \sin^{2}\Theta\right) + B_{i} \exp(-b_{i}/\lambda^{2} \sin^{2}\Theta) + C_{i} \exp(-c_{i}/\lambda^{2} \sin^{2}\Theta) + D_{i}$$

The constants  $A_i$ ,  $B_i$ ,  $C_i$  and  $a_i$ ,  $b_i$ ,  $c_i$  have been calculated by Appel  $^6$  on the basis of atomic scattering factor tables given by Tomas and Umeda  $^7$  for ruthenium and by Ibers 8 for boron.

	$\boldsymbol{A}$	$\boldsymbol{B}$	$oldsymbol{C}$	$\boldsymbol{a}$	b	$\boldsymbol{c}$
Ruthenium Boron	$15.176 \\ 1.644$	$\begin{array}{c} 16.599 \\ 0.406 \end{array}$	$\frac{11.760}{2.878}$	$0.240 \\ 0.6069$	$2.637 \\ 4.5832$	$20.292 \\ 33.019$

The real part of the dispersion correction for ruthenium  $(D_i$  in the expression above) was obtained from the table of Dauben and Templeton 9.

## RESULTS

The powder photograph of the alloy from which the actual single-crystal specimen was selected, gave the following dimensions of the orthorhombic unit cell:

$$a = 11.60_9 \text{ Å}, \qquad b = 11.34_2 \text{ Å}, \qquad c = 2.83_6 \text{ Å and } U = 373.4 \text{ Å}^3.$$

Small variations of the lattice parameters (0.2 %) have been observed. It is evident from powder and single-crystal data that  $\mathrm{Ru}_{11}\mathrm{B}_8$  is orthorhombic. Since 0kl reflexions appear only for k=2n, and k0l reflexions only for h = 2n, and no limiting conditions are found for hkl,hk0 and 00l reflexions, the most probable space-groups are Pbam and Pba2. The distribution of intensities in the hk0 and hk2 zones are similar, apart from the normal decline. This distribution of intensities indicates that the ruthenium atoms are situated in planes perpendicular to the c-axis with a spacing of c/2. For that reason, only the  $|F|^2$  values for hk0 and hk1 reflexions were necessary for evaluating the Patterson sections P(UV0) and P(UV1/2). The analysis of these sections showed that the heights and positions of all large peaks in P(UV0) and P(UV)1/2) could be interpreted by assuming the space-group to be *Pbam* with twenty ruthenium atoms in five fourfold positions and two ruthenium atoms in a twofold position. If the twofold position 2(a) is chosen, twelve ruthenium atoms are situated in three fourfold positions 4(g) and eight ruthenium atoms in two

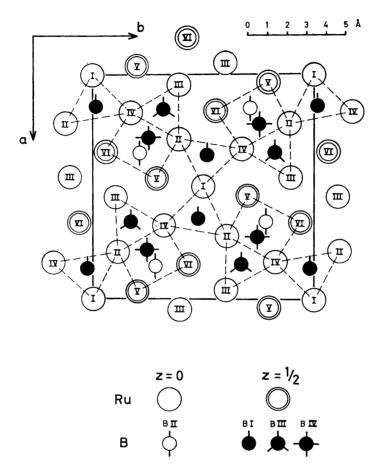

Fig. 1. The structure of Ru<sub>11</sub>B<sub>8</sub> projected on the ab-plane.

fourfold positions 4(h). During the refinement of the structure nothing was found to contradict the choice of the space-group Pbam. (Small deviations from this symmetry for the boron positions cannot be excluded.)

Starting with the rough parameter values obtained from the Patterson maps, signs were calculated for the observed F(hk0) values, and the electron density projection  $\varrho$  (xy) was computed. The x and y coordinates of the ruthenium atoms were refined from successive difference syntheses. After the final refinement of the ruthenium coordinates, the R value 0.105 was obtained for the observed 310 independent hk0 reflexions when an empirical isotropic temperature factor with  $B=0.23_0$  Ų was applied. No corrections for absorption and extinction were made.

In the final difference synthesis map, in which all ruthenium atoms were subtracted, four rather well resolved boron maxima were visible. Three of

Table 1. Final atomic parameters of  $Ru_{11}B_8$ . Space-group *Pbam*. (The standard deviation for all Ru-coordinates is  $\pm 0.0002$ .)

2 Ru <sub>I</sub> 4 Ru <sub>II</sub> 4 Ru <sub>II</sub> 4 Ru <sub>IV</sub> 4 Ru <sub>V</sub> 4 Ru <sub>V</sub>	in 2(a) in 4(g) in 4(g) in 4(g) in 4(h) in 4(h)	$x_{ ext{II}} = 0.2844$ $x_{ ext{III}} = 0.0429$ $x_{ ext{IV}} = 0.1686$ $x_{ ext{V}} = 0.4636$ $x_{ ext{VI}} = 0.3404$	$y_{\text{II}} = 0.3913$ $y_{\text{III}} = 0.3952$ $y_{\text{IV}} = 0.1740$ $y_{\text{V}} = 0.2962$ $y_{\text{VI}} = 0.0616$
4 B <sub>I</sub> 4 B <sub>II</sub> 4 B <sub>III</sub> 4 B <sub>IV</sub>	in $4(h)$ in $4(g)$ in $4(h)$ in $4(h)$	$egin{array}{ll} x_{ m I} &= 0.13_{ m 98} \ x_{ m II} &= 0.34_{ m 79} \ x_{ m III} &= 0.15_{ m 23} \ x_{ m IV} &= 0.27_{ m 99} \end{array}$	$\begin{array}{lll} y_{\rm I} &= 0.01_{\rm 81} \\ y_{\rm II} &= 0.21_{\rm 56} \\ y_{\rm III} &= 0.32_{\rm 65} \\ y_{\rm IV} &= 0.25_{\rm 35} \end{array}$

these maxima, corresponding to one 4(g) position and three 4(h) positions had about the same height, but the  $B_{IV}$  maxima was considerably lower and not symmetrical in shape. Only one other maximum of the same height as the boron maxima was found, but space considerations showed that this maximum could not be a boron maximum.

With the same temperature factor ( $B = 0.23_0$  Å<sup>2</sup>) and with all atoms subtracted, a final refinement cycle was made. The reliability index of the observed 310 independent hk0 reflexions was found to be 0.097. A list of calculated and observed structure factors can be obtained from this Institute on request.

Acta Chem. Scand. 14 (1960) No. 10

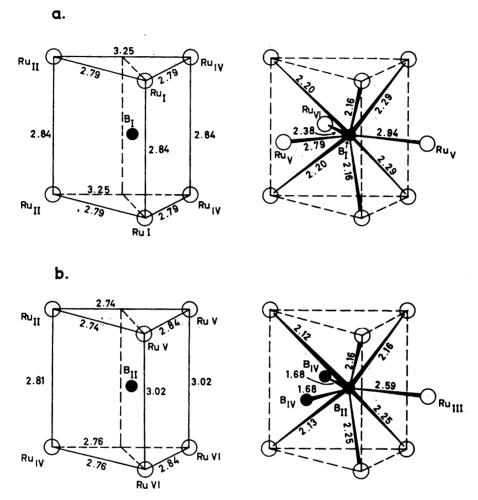

Fig. 3. The environment of the boron atoms in  $\mathrm{Ru_{11}B_8}$ .

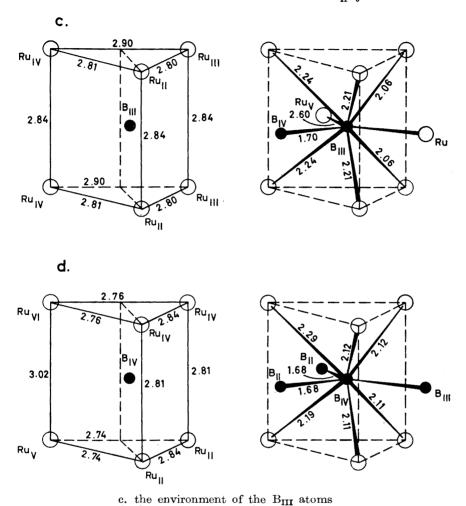

a. the environment of the  $\mathrm{B_I}$  atoms
b. the environment of the  $\mathrm{B_{II}}$  atoms

The final atomic parameters with standard deviations and interatomic distances are listed in Tables 1 and 2. (The standard deviations of the atomic parameters of ruthenium were estimated with Cruickshank's <sup>10</sup> formula.)

## DESCRIPTION OF THE STRUCTURE

A projection of the structure on the *ab*-plane is shown in Fig. 1. From the crystal-chemical point of view, the structure of Ru<sub>11</sub>B<sub>8</sub> shows many resemblances to the orthorhombic Ni<sub>4</sub>B<sub>3</sub> structure described by Rund-

Acta Chem. Scand. 14 (1960) No. 10

qvist <sup>11</sup>. Both structures can be described as built-up by interconnected trigonal prisms of metal atoms, with the boron atoms situated in the centers of these prisms. The metal atoms have ten or eleven neighbours of their own kind, and the boron atoms have the usual triangular prismatic environment.

d. the environment of the B<sub>IV</sub> atoms

In both the structures the boron atoms are partly isolated without close boron contacts, partly connected to infinite zig-zag chains running throughout the structure in the direction of the shortest axis.

The boron chains in orthorhombic Ni<sub>4</sub>B<sub>3</sub> are single zig-zag chains of the same type as the chains in the MeB-borides of the FeB-, MoB- and CrB-types <sup>12</sup>. Every boron atom in the chains is in close contact with two other boron atoms.

Acta Chem. Scand. 14 (1960) No. 10

In the boron zig-zag chains in Ru<sub>11</sub>B<sub>8</sub> every second boron atom is in close contact with two other boron atoms and every second boron atom is in close contact with three other boron atoms (see Fig. 2 b). In the borides of composition Me<sub>3</sub>B<sub>4</sub><sup>12</sup> the boron atoms form double chains.

The boron chain in Ru<sub>11</sub>B<sub>8</sub> can be looked upon as a transition type between

a single chain and a double chain.

For comparison a single chain in FeB13 and a double chain in Mn<sub>3</sub>B<sub>4</sub>14 are shown in Figs. 2 a and 2 c.

The four types of trigonal ruthenium atom prisms are shown in Figs. 3 a, b, c and d together with the environments of the B<sub>I</sub>, B<sub>II</sub>, B<sub>III</sub> and B<sub>IV</sub> atoms.

The coordination number of the boron atoms is nine, the B<sub>I</sub> atoms have nine ruthenium neighbours, the B<sub>III</sub> atoms have eight ruthenium neighbours and one boron neighbour, the B<sub>II</sub> atoms have seven ruthenium neighbours and two boron neighbours and the B<sub>IV</sub> atoms have six ruthenium neighbours and three boron neighbours.

The metal-metal distances are normal with an average distance of 2.79 Å. The average of the twentyfour shortest ruthenium-boron distances is 2.18 Å. This value is in good agreement with the sum, 2.21 Å, of the normal atomic radius of boron, 0.87 Å (Kiessling 12) and the atomic radius of ruthenium for coordination number 12, 1.34 Å.

Acknowledgements. I wish to thank Professor G. Hägg for his kind interest and for all facilities put at my disposal.

I also want to thank Drs. B. Aronsson, R. Hesse and S. Rundqvist for introducing

me into this interesting field of science.

Thanks are also due Mr E. Stenberg for many stimulating discussions.

Financial support is gratefully acknowledged from the Air Force Office of Scientific Research and Development Command, United States Air Force, through its European Office under Contract No. AF 61(052)-40 and from the Swedish Technical Science Research Council. Facilities for use of the electronic digital computer BESK were given by the Swedish Board for Computing Machinery.
