Studies of Metal Complexes of Radiobiological Interest

I. The Acidity Constants of Croconic Acid

BIRGER CARLQVIST and DAVID DYRSSEN*

The Research Institute of National Defence, Dept. 4 (FOA 4), Stockholm 90, Sweden

Potentiometric and spectrophotometric methods were used for the determination of the dissociation constants of croconic acid at 25°C. The potentiometric method gave only approximate values of $pK_1 = 0.3 - 0.5$ and $pK_2 = 1.4 - 1.6$ (2 M H$_3$Na(Cl) and $pK_1 = 0.6$ and $pK_2 = 1.8$ (0.1 M H$_3$Na Cl).

The ultraviolet spectra of croconic acid have been determined in mixed solutions of 2 M HCl and 2 M NaCl. The absorption data were treated by two methods:

(a) The graphical method for determining the four unknown parameters in eqn. (9) by testing reasonable values of the molar extinction coefficients of H$_3$A and HA$^-$. The slope and intercept of the best straight lines corresponded to $pK_1 = 0.2 - 0.3$ and $pK_2 = 1.3 - 1.5$.

(b) The least squares technique using a high-speed digital computer for determining a set of parameters giving the minimum standard deviation. This minimum was obtained for $pK_1 = 0.32$ and $pK_2 = 1.51$. In addition the spectra for the H$_3$A and HA$^-$ forms of croconic acid were obtained by this method.

In recent years, the coordination chemistry of the alkaline earth metals has attracted special interest due to the occurrence of strontium and barium among the fission products of heavy atoms. Since soluble calcium or strontium chelates have proved to have little or no effect in eliminating strontium from the living body, attention has been turned to more insoluble complexes.

It has been known for a long time that strontium rhodionate (SrC$_4$O$_6$) is less soluble than the calcium salt (see, e.g., Weiss and Shipman$^1$) and this fact has encouraged the use of sodium rhodinate in biochemical investigations. Rhodinate solutions (especially acid solutions) are, however, not very stable, thus preventing wider use of this reagent. One of the decomposition products is croconic acid, which is a homologous compound with a 5 membered ring. Croconate solutions seem to be more stable than rhodionate solutions.

* Present address: Department of Inorganic Chemistry, Royal Institute of Technology, Stockholm 70, Sweden.

Acta Chem. Scand. 16 (1962) No. 1
The acidity constants of croconic acid are not accurately known. Carpeni\(^2\) has reported the values of \(pK_1\) and \(pK_2\) to be 2.17 and 4.0 from potentiometric data, but quite different from this, Yamada, Mizuno and Hirata\(^3\) have roughly estimated \(pK_1<1 <pK_2<2\) from spectrophotometric measurements. For a study of the complex chemistry of croconic acid a more accurate determination of these dissociation constants is therefore desirable. Both the potentiometric and the spectroscopic methods have been investigated here and the latter method has proved to give more reliable values of \(K_1\) and \(K_2\).

**EXPERIMENTAL**

Potassium croconate was prepared by oxidation of sodium rhodizinate in alkaline solution according to the method of Nietzki and Benckiser\(^4\). Either oxygen was bubbled through the rhodizinate solution in 1 M KOH at 60°-70° for a few hours, or sodium rhodizinate was oxidized with MnO\(_4^-\) in a solution of potassium carbonate (cf. Yamada, Mizuno and Hirata\(^5\)). The crystals formed after cooling were filtered off. The filtrate was evaporated and more crystals were obtained. The salt was recrystallized twice from water and dried at 110°. Combustion with \(V_2O_5\) as catalyst gave a carbon content of 27.8 % (no hydrogen). Calculated for \(C_4O_4K_2\): 27.5 %. Yield ca. 50 %.

The potentiometric titrations of \([H^+]\) were carried out at 25°C in a thermostated room. The emf was measured with a Radiometer pH Meter 4 using a Radiometer G 202 B glass electrode. The titrations of dipotassium croconate (\(K_2A\)) were carried out with 50 – 150 ml of 2 M or 0.1 M (H, Na)Cl in 2 M or 0.1 M NaCl solutions using a common saturated KCl/HgCl\(_2\) Hg electrode as a reference. The cells were standardized against solutions of known \(-\log[H^+]\) and constant ionic strength (0.1 M and 2 M, respectively).

The light absorption measurements were made with a Zeiss PMQ II spectrophotometer with 1 cm quartz cells. In neutral or alkaline solutions the absorption was fairly stable but it decreased slowly in weakly acid solutions. This decrease was especially rapid in strong HClO\(_4\), whereas 89 % of the initial absorption still remained after 7 days in 5 M HCl.

**LIST OF SYMBOLS**

- \([\text{ }]\) concentrations
- \([A]_{tot}\) total concentration of croconic acid (3)
- \(H_2A, HA^-, A^2-\) croconic acid and croconate ions
- \(D\) optical density = extinction (6)
- \(E\) electromotive force in mV
- \(I\) ionic strength
- \(K_1, K_2\) stoichiometric acid dissociation constants (7)
- \(K_{av}\) average dissociation constant (5)
- \(m\) number of different wave-lengths (14)
Fig. 1. Potentiometric titration of 1 mmole of croconic acid (obtained by ion-exchange of the dipotassium salt) with 0.1 M NaOH.

\( n \)  
number of experimental points in least squares calculation

\( \bar{n} \)  
formation function according to Bjerrum.

\( Z \)  
average number of H bound per A (1)

\( \varepsilon \)  
overall molar extinction coefficient (9)

\( \varepsilon_0, \varepsilon_1, \varepsilon_2 \)  
molar extinction coefficients (6)

\( \lambda \)  
wave-length in \( \text{m} \mu \)

\( \sigma_\lambda \)  
standard deviation in \( \varepsilon \) at a certain wavelength (13)

\( \sigma_{\text{tot}} \)  
standard deviation in \( \varepsilon \) for nine wave-lengths (14)

**RESULTS**

The determination of \( Z \) function from potentiometric titrations. From the potentiometric titration curve (Fig. 1) it is quite evident that croconic acid is highly dissociated even at very low pH values. The acid is dibasic but the two dissociation steps are so close that they do not appear in Fig. 1. The average number of hydrogen atoms bound to the croconate ion is defined by:

\[
Z = \frac{2[H_2A] + [HA^-]}{[A]_{\text{tot}}}
\]  

(1)

*Acta Chem. Scand.* 16 (1962) No. 1
The concentration of $\text{H}_2\text{A}$ and $\text{HA}^-$ were computed using the law of electroneutrality (ionic medium not included):

$$[\text{K}^+] + [\text{H}^+] = [\text{Cl}^-] + [\text{HA}^-] + 2[A^{2-}]$$  \hspace{1cm} (2)

where $[\text{K}^+] = 2[A]_{\text{tot}}$ and $[\text{Cl}^-]$ is the amount of HCl added.

The total concentration of croconic acid in all its forms is

$$[\text{A}]_{\text{tot}} = [\text{H}_2\text{A}] + [\text{HA}^-] + [A^{2-}]$$  \hspace{1cm} (3)

From (1), (2) and (3) it follows that

$$Z = \frac{[\text{Cl}^-] - [\text{H}^+]}{[\text{A}]_{\text{tot}}}$$  \hspace{1cm} (4)

There is a close relation between the formation function, $\tilde{n}$, for the complex formation described by Bjerrum \(^5\) and the $Z$ function for polyvalent acids (cf. Sillén \(^6\)). Thus the ligands of a complex correspond to the protons and the central metal atom to the anion of the acid. If $\tilde{n}$ is plotted versus the logarithm of the ligand concentration curves are obtained with the same form as plots of $Z$ against $\log [\text{H}^+]$. The "average" constant may be calculated from the midpoint of this curve. Regardless of the number of ligands or the difference between the individual constants, Bjerrum \(^5\) has shown that the average formation constant is equal to the reciprocal ligand concentration at the midpoint provided the formation curve is symmetrical.

In a similar way, one can prove that the average dissociation constant, $K_{av}$, is equal to the hydrogen ion concentration at the midpoint of the $Z$ function. In the special case of a dibasic acid we thus have

$$pK_{av} = \frac{1}{2} (pK_1 + pK_2) = -\log [\text{H}^+]_m$$  \hspace{1cm} (5)

where $[\text{H}^+]_m$ refers to the midpoint value of $Z = 1$. When the ratio between $K_1$ and $K_2$ is large (about 10 000 or more) the two steps are separated and

---

**Fig. 2.** $Z$-data (see text) as a function of $-\log [\text{H}^+]$ for 2 M (H$_2$Na)Cl: $\bigcirc$ (5 mmols of K$_2$A), $\bigtriangleup$ (1 mmole of K$_2$A), and 0.1 M (H$_2$Na)Cl: $\Box$ (1 mmole of K$_2$A). The normalized curve $Y = (p v + 2 v^2)/(1 + pv + v^2)^2$, $X = \log v$ with $p = 4$ (full-drawn curves) and $p = 3$ (dashed curve) are fitted to the data (cf. Sillén \(^6\)).

*Acta Chem. Scand.* 16 (1962) No. 1
Fig. 3. Spectra of $4 \times 10^{-4}$ M croconic acid in 2 M (H,Na)Cl. The following numbers refer to curves at different [H$^+$]: 1, 1.98 M; 2, 0.98 M; 3, 0.50 M; 4, 0.22 M; 5, 0.11 M; 6, 0.050 M; 7, 0.022 M; 8, 0.01 M; 9, 0.001 M; 10, $10^{-4}$ M. Curve 1 has maximum at 299 m$\mu$ and curve 9 at 363 m$\mu$.

under these conditions, $pK_1$ and $pK_2$ are equal to $-\log [H^+]$ at $Z = 1.5$ and 0.5, respectively. However, if the constants are close to each other two steps cannot be seen in the Z-curve (cf. Sillén 6).

From the titration without croconate, all other conditions being unchanged, the calibration curve of $E$ versus $-\log[H^+]$ was obtained. Fig. 2 shows the $Z$ function at 0.1 M and 2 M ionic strength. It was impossible to obtain the complete curves due to the inaccuracy of the $Z$ values in strong acid solutions.

By curve-fitting (cf. Sillén 6) we could estimate: $pK_1 \simeq 0.6$, $pK_2 \simeq 1.8$ in 0.1 M (H,Na)Cl, and $pK_1 = 0.3-0.5$ and $pK_2 = 1.4-1.6$ in 2 M (H,Na)Cl. The latter values agree with the spectrophotometric measurement below.

Spectrophotometric determination of $K_1$ and $K_2$. In the main series, the [H$^+$] covered the range from 2 M HCl to 2 M NaOH and the ionic strength was kept constant at 2.0 M with NaCl. In Fig. 3 the spectra are shown for $4 \times 10^{-4}$ M total croconic acid in 2 M (H,Na)Cl. There is very little change in the spectra below [H$^+$] = 0.001 M, which shows that croconic acid is a rather strong acid.

The two isosbestic points (at ca. 310 and ca. 325 m$\mu$) are not sharp, and they indicate that there are three different species of croconic acid. In strong acid (5 or 12 M HCl) or alkaline solvent effects seem to occur; these spectra are not included in Fig. 3 (cf. Fig. 4). At a certain wave-length the optical density, $D$, is the sum of the absorption of all forms of croconic acid

$$D = \varepsilon_0[H_2A] + \varepsilon_1[HA^-] + \varepsilon_2[A^-] \quad (6)$$

where $\varepsilon_0$, $\varepsilon_1$, and $\varepsilon_2$ are the molar extinction coefficients of the forms $H_2A$, $HA^-$ and $A^-$, respectively (cell of unit length = 1 cm).
Fig. 4. Variation of optical density, \( D \), for \( 4 \times 10^{-5} \) M croconic acid with acidity at four different wave-lengths (the two maxima and the two isosbestic points).

The stoichiometric dissociation constants are

\[
K_1 = \frac{[\text{H}^+][\text{HA}^-]}{[\text{H}_2\text{A}]} \quad \text{and} \quad K_2 = \frac{[\text{H}^+] [\text{A}^{2-}]}{[\text{HA}^-]} \tag{7}
\]

Combining eqns. (3), (6) and (7) one can derive the relation

\[
D[A]_{\text{tot}}^{-1} = \frac{[\text{H}^+]^2 \varepsilon_o + K_1[\text{H}^+] \varepsilon_1 + K_1 K_2 \varepsilon_2}{[\text{H}^+]^2 + K_1[\text{H}^+] + K_1 K_2} \tag{8}
\]

Eqn. (8) can be rearranged to a form more suitable for numerical calculations

\[
\frac{(\varepsilon - \varepsilon) [\text{H}^+]^2}{(\varepsilon - \varepsilon_2)} = \frac{(\varepsilon - \varepsilon_1)}{(\varepsilon - \varepsilon_2)} [\text{H}^+] K_1 + K_1 K_2 \tag{9}
\]

where \( \varepsilon = D[A]_{\text{tot}}^{-1} \) is obtained experimentally. There is no direct way in which \( \varepsilon_1 \) can be obtained and \( \varepsilon_o \) is not accurately known since some HA\(^-\) still exists in the most acid solution, 2 M HCl (Fig. 4). A graphical method was used for evaluating \( K_1 \) and \( K_2 \) from eqn. (9) which may be written as linear equation

\[
Y = K_1 X + K_1 K_2 \tag{10}
\]

where \( Y = \frac{\varepsilon - \varepsilon_o}{\varepsilon - \varepsilon_2} [\text{H}^+]^2 \) and \( X = \frac{\varepsilon - \varepsilon_1}{\varepsilon - \varepsilon_2} [\text{H}^+] \).

Plots were made of \( Y \) versus \( X \) for combinations of reasonable values of \( \varepsilon_o \) and \( \varepsilon_1 \) for the two peaks at 363 m\( \mu \) and 299 m\( \mu \). The best fit with a straight line was obtained for \( \varepsilon_o = 1.0 \times 10^3 \) and \( \varepsilon_1 = (13-15) \times 10^3 \) at 363 m\( \mu \) and

$pK_1 = 0.2 - 0.3$
$pK_2 = 1.3 - 1.5$

for $\epsilon_0 = 15.5 \times 10^2$ and $\epsilon_1 = (5-7) \times 10^2$ at 299 m$\mu$. The slope of these lines corresponds to $K_1$. The intercept on the horizontal axis is $-K_2$ and that on the vertical axis is $K_1K_2$. The results are summarized in Table 1. On the whole this method is rather time-consuming even if a desk-calculator is employed.

Thamer and Voigt 7 have developed a method for determining overlapping dissociation constants for dibasic acids if $\epsilon_0$ and $\epsilon_1$ can be obtained by direct measurement at low and high pH values. This method fails, however, in our case since the absorption does not reach a limiting value in the strong acidic region.

In order to obtain more accurate results, the data were treated by the method of least squares. These calculations are very time-consuming unless a high-speed digital computer is employed. In cooperation with Mr. Kurt Eriksson at the FOA division of applied mathematics a program 8 was developed for the FACIT EDB computer to calculate the best values of the 4 constants $K_1$, $K_2$, $\epsilon_0$ and $\epsilon_1$ from eqn. (8). The input data were the values of $[H^+]$, $\epsilon_2$ and the "over all" molar extinction coefficient, $\epsilon = D[A]_{\text{tot}}^{-1}$, for 9 different wave-lengths.

In the first place we investigated the possibility of a direct estimation of all four parameters. At certain wavelengths, however, some of the parameters turn out to be negative.

The program was changed so that the values of $\epsilon_0$ and $\epsilon_1$ would be calculated by the method of least squares for a series of reasonable values of $K_1$ and $K_2$. This approach is in a way closely related to the "error-pit" calculation method by Dyrssen, Ingri and Sillén 9. Since the dissociation constants are independent of the wave-length they were used as input data. Eqn. (8) can be written in the form

$$D[A]_{\text{tot}}^{-1} = \epsilon = f ([H^+]) \quad (11)$$

where the dependent variable, $\epsilon$, is subject to random errors; the error in $[H^+]$ can be neglected. The least squares method requires that a set of parameters be determined which minimizes

$$A \epsilon = [\epsilon - f ([H^+])] \quad (12)$$

$\sigma_{\text{tot}} = 0.2721$

*Acta Chem. Scand. 16 (1962) No. 1*
The standard deviation in $\varepsilon$ at a certain wave-length for eight different $[\text{H}^+]$ (Fig. 3) is

$$\sigma_\lambda = \left[ \frac{1}{n(n-1)} \right]^{\frac{1}{2}} \left[ \frac{\sum \Delta \varepsilon^2 - \frac{1}{n} \left( \sum \Delta \varepsilon \right)^2}{n} \right]^{\frac{1}{2}} (n=8) \quad (13)$$

The corresponding standard deviation taken over all wave-lengths is

$$\sigma_{\text{tot}} = \left( \frac{1}{m} \right)^{\frac{1}{2}} \left[ \sum \sigma_\lambda^2 \right]^{\frac{1}{2}} (m=9) \quad (14)$$

Input data: $\varepsilon = D[A]_0^{-1} [\text{H}^+], \varepsilon_1, \sigma_\lambda, \sigma_{\text{tot}}$.  
Output data: $\varepsilon_0, \varepsilon_1, \sigma_\lambda, \sigma_{\text{tot}}$.

In the first computation, the values of $K_1$ were 1, 0.5 and 0.1 and those of $K_2$ were 0.1, 0.05 and 0.01 (nine combinations). A lowest value of $\sigma_{\text{tot}}$ (nine wave-lengths, cf. Table 2) was obtained for the pair $K_1 = 0.5$ and $K_2 = 0.05$.

Three other computations were made with the following $K$-values:

(II) $K_1$: 0.3, 0.4, 0.5, 0.6, 0.7 and 0.8
     $K_2$: 0.02, 0.03, 0.04, 0.05, 0.06 and 0.07
     36 combinations

(III) (only for $\lambda = 363\,\mu$)
     $K_1$: 0.40, 0.45, 0.50, 0.55 and 0.60
     $K_2$: 0.026, 0.028, 0.030, 0.032 and 0.034
     25 combinations

(IV) (nine wave-lengths)
     $K_1$: 0.48
     $K_2$: 0.031.

Fig. 5 shows the relation between $\sigma_{tot}$ and the various combinations of $K_1$ and $K_2$. The minima corresponded to $K_1 \simeq 0.5$ and $K_2 \simeq 0.03$. The plots of the standard deviations for a specific wave-length may give sharper minima, in this case at $\lambda = 363\,\mu$ (Fig. 6). The results from the computation III with narrow intervals of $K_1$ and $K_2$ at $\lambda = 363\,\mu$ are shown in Fig. 7. The least standard deviation from these curves corresponded to $K_1 = 0.48$ and $K_2 = 0.031$. Finally, the calculations were made with this pair of $K$ values over the whole spectrum in order to get the spectra for the three forms of croconic acid (Table 2 and Fig. 8).

In Table 3 we have collected values of the dissociation constants of croconic acid. Both our work and the investigation of Yamada, Mizuno and Hirata$^3$ show that the $K$-values found by Carpéni$^2$ are probably erroneous.
