The Crystal Structures of Cs₂MnCl₄,2H₂O and Rb₂MnCl₄,2H₂O

STIG JORGO JENSEN

Department of Technology, The Royal Dental College, Aarhus C, Denmark

Cs₂MnCl₄,2H₂O and Rb₂MnCl₄,2H₂O are isomorphous and crystallize in the triclinic system; space group $P\overline{1}$ with a=5.74 Å, b=6.66 Å, c=7.27 Å, $\alpha=67.0^{\circ}$, $\beta=87.8^{\circ}$, $\gamma=84.3^{\circ}$ for Cs₂MnCl₄,2H₂O, and a=5.66 Å, b=6.48 Å, c=7.01 Å, $\alpha=66.7^{\circ}$, $\beta=87.7^{\circ}$, $\gamma=84.8^{\circ}$ for Rb₂MnCl₄,2H₂O. There is one formula unit per unit cell. The structures were determined from two-dimensional Patterson projections. Each manganese atom is octahedrally coordinated to four chlorine atoms and two water molecules. The water molecules occupy trans-positions.

CsMnCl₃,2H₂O is formed at 20°C from aqueous solutions containing 0.01 mole CsCl and 0.01 mole MnCl₂.¹ Another hydrate, Cs₂MnCl₄,2H₂O, is formed in a similar way from solutions containing 0.02 mole CsCl and 0.01 mole MnCl₂. From aqueous solutions containing RbCl and MnCl₂ only one compound, Rb₂MnCl₄,2H₂O, is formed at 20°C. The crystal structure of CsMnCl₃,2H₂O has previously been reported.¹ A previous note ² communicated preliminary results from an X-ray investigation of Cs₂MnCl₄,2H₂O and Rb₂MnCl₄,2H₂O. The crystal structures of these compounds were determined to investigate the coordination around the manganous ion and the location of the water molecules. Saunders ²a reported the existence of the three double halides.

EXPERIMENTAL

Cs₂MnCl₄,2H₂O was prepared from an aqueous solution containing 0.02 mole CsCl and 0.01 mole MnCl₂,4H₂O (Merck p.a.) and slow evaporation at 20°C. The crystals formed pale pink prisms elongated along the [011] direction. Chemical analysis gave the following results: Mn 10.90; Cl 28.25; H₂O 7.55; Cs 53.30. Calc. for Cs₂MnCl₄,2H₂O: Mn 11.01; Cl 28.45; H₂O 7.23; Cs 53.31. Mn was determined by complexometric titration with EDTA, Cl by potentiometric titration using AgNO₃, and the water gravimetrically by heating to 105°C. Cs was calculated as the balance. The crystals decompose at 84°C. The density was 3.23 g/cm³ (20°C) as measured by flotation in a mixture of acetylene tetrabromide and methylene iodide.

Rb₂MnCl₂,2H₂O was prepared in a similar way using RbCl and MnCl₂,4H₂O and showed the same shape and colour as the cesium compound. Chemical analysis gave:

Acta Chem. Scand. 18 (1964) No. 9

Mn 13.49; Cl 34.78; H₂O 9.08; Rb 42.65. Calc. for Rb₂MnCl₄,2H₂O: Mn 13.60; Cl 35.13; H₂O 8.92; Rb 42.35. The crystals decompose at 93°C. The density was 2.81 g/cm³ (20°C) as measured in a mixture of carbon tetrachloride and acetylene tetrabromide.

Unit cell dimensions were determined from Guinier powder diagrams using CsCl or RbCl as reference. Fe $K\alpha$ radiation was employed. The choice of unit cell in the triclinic system followed the rules according to the Dirichlet reduced cell (Balashov and Ursell 3): |a| < |b| < |c|, where a, b, and c are the three shortest noncoplanar translations.

α, β, and γ are homogeneous, i.e. either all acute or all obtuse. The powder diagrams showed that Cs₂MnCl₄,2H₂O and Rb₂MnCl₄,2H₂O are probably isostructural.

Microscopic and X-ray examinations of crystals of Cs₂MnCl₄,2H₂O and Rb₂MnCl₄,2H₂O revealed that they were generally twinned with twin-axis normal to (011). For intensity measurements crystal fragments, which appeared to be untwinned, were used. The dimensions of the Cs₂MnCl₄,2H₂O-crystals were 0.060 \times 0.150 \times 0.400 mm³ and 0.050 \times 0.150 \times 0.200 mm³ and the dimensions of the Rb₂MnCl₄,2H₂O-crystals were 0.050 \times 0.300 \times 0.200 mm³ and 0.050 \times 0.100 \times 0.200 mm³. Because of the rather high absorption coefficients of the crystals (μ Cs₂MnCl₄,2H₂O = 100 cm⁻¹ and μ Rb₂MnCl₄,2H₂O = 100 cm⁻¹ for M ν C, and because of their elements of the crystals are of their elements of the crystals coefficients of the crystal 139 cm⁻¹ for $MoK\alpha$) and because of their shape, intensity measurements are affected by absorption errors. It was not possible due to clevage to grind the crystals to a more

ideal shape. However, no correction for absorption was applied.

The h0l and 0kl reflexions were recorded with the smaller Cs₂MnCl₄,2H₂O- and Rb₂MnCl₄,2H₂O-crystals and the hk0 reflexions with the bigger crystals. Integrated Weissenberg photographs were prepared using $MoK\alpha$ radiation. The multiple film technique with Ni-foil interleaves was employed. The intensities of the reflexions were measured on a Joyce-Loebl double-beam densitometer and corrected for Lorentz- and polarization-factors using a digital computer. The crystals showed no piezo-electric effect. Thus a centre of symmetry might be present.

STRUCTURE DETERMINATION OF Cs,MnCl,,2H,O

The unit cell contains one unit of Cs₂MnCl₄,2H₂O. Thus the Mn-atom must occupy a special position if a centre of symmetry is present. The parameters of the cesium and of the manganese atoms were obtained from (100) and (010) Patterson projections. When the Cs-atom is placed in x, y, z and -x, -y, -z, the Mn-atom must be at 0, $\frac{1}{2}$, $\frac{1}{2}$ and the space group $P\overline{1}$ is possible. The signs of the structure factors F(h0l) and F(0kl) were calculated from the contributions of the Cs- and Mn-atoms. The positions of the Cland O-atoms were obtained from Fourier projections along the a- and baxes using these signs.

For refinement a method suggested by Bhuiya and Stanley 4 was used. The geometric parameters and individual isotropic temperature factors of each atom are varied in turn and the values yielding the lowest residual factor, $R = \Sigma ||F_{o}| - |F_{c}||/\Sigma |F_{o}|$, are chosen. For the computations an Algol-programme written for the computer GIER by Danielsen 5 was used.

The atomic scattering factors were calculated by means of the following expression according to Bassi:6

$$f(x) = N - \frac{x}{a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4}$$

where $x = \sin \theta / \lambda$ and N = the atomic number of the atom. The parameters used are given in Table 1.

The h0l, 0kl, and hk0 reflexions were first refined individually. A series of 6 cycles of refinements was computed for each projection. The R-values

	N	a_{0}	a_{1}	a_2	a_3	a_4
Cs	55	2.4224×10 ⁻³	-3.2128×10^{-3}	6.5857×10^{-2}	-8.3668×10^{-2}	4.9582
$\mathbf{R}\mathbf{b}$	36	4.5857×10^{-3}	-7.1539×10^{-3}	7.7647×10^{-2}	-6.2351×10^{-2}	2.7202×10^{-2}
$\frac{1}{2}Mn$	$12\frac{1}{2}$	4.5925×10^{-3}	2.8568×10^{-2}	1.0014×10^{-1}	-1.2940×10^{-1}	1.1959×10^{-1}
Cl	17	5.3006×10^{-3}	3.1046×10^{-3}	2.0229×10^{-2}	1.9064×10^{-1}	-1.5990×10^{-1}
0	8	1.1906×10^{-2}	5.1983×10^{-3}	8.1682×10^{-2}	9.5267×10^{-2}	-4.2875×10^{-2}

Table 1. Parameters for the atomic scattering factor.

were reduced from R(h0l)=43 %, R(0kl)=20.9 % and R(hk0)=14.7 % to R(h0l)=9.7 %, R(0kl)=8.7 % and R(hk0)=10.7 % excluding all non-observed reflexions. Difference Fourier projections were evaluated at this stage. In the h0l- and hk0-difference synthesis small peaks and troughs of electron density could be seen around the Cs-atom. This is probably due to absorption effects. Because of the rather small R-values no attempt was made to eliminate these anomalies. Finally the three projections were refined together leaving an R-value at 9.9 %.

STRUCTURE DETERMINATION OF Rb2MnCl,2H2O

The powder pattern of Rb_2MnCl_4 , $2H_2O$ shows that the structure of this compound is probably the same as that of Cs_2MnCl_4 , $2H_2O$. Therefore the Rb-and Mn-atoms were given the same coordinates as the Cs- and Mn-atoms in the analogous cesium compound. Structure-factors were calculated from the contributions of these atoms. Fourier projections along the a- and b-axis using signs from the structure factor calculation gave the positions of the Cl- and O-atoms.

The Bhuiya-Stanley method of refinement was also used for Rb₂MnCl₄, 2H₂O. The parameters for the atomic scattering factor for rubidium are recorded in Table 1. A series of 6 cycles of refinements was calculated for each projection. The R-values were reduced from R(0kl) = 18.2 %, R(hk0) = 17.3 %and R(h0l) = 15.6 % to R(0kl) = 8.8 %, R(hk0) = 13.4 % and R(h0l) = 12.9 %. Data from the three projections refined together gave R(hkl) = 11.9 %. The neglect of absorption errors is a probable explanation of the fact that the R(hk0) and R(h0l) values are greater than the R(0kl)-value. When the crystal is oriented along the c-axis the maximum and minimum dimensions at right angles to the axis of rotation are 0.300 mm and 0.050 mm. Difference Fourier projections evaluated at this stage confirmed this assumption. Anomalies of the patterns indicative of improper anisotropic absorption allowance were observed around the Rb-atom and to a small extent around the other atoms in the hk0- and h0l-projection. These anomalies appeared especially in the hk0-projection (Fig. 1). To improve the accuracy of the positions of the lighter atoms a method suggested by Kartha and Ahmed 7 was used. In the next cycle of refinement the rubidium atom was represented in the structure factor calculations by two isotropic, fractional atoms placed symmetrically around

the atom centre with the coordinates (0.214, 0.165, 0.117) and (0.264, 0.165, 0.117). By this method R(hk0) was reduced to 10.6 % and R(h0l) to 11.8 %. In difference projections evaluated after these calculations were carried out the anomalies practically disappeared. Finally all observed data were refined together leaving an R-value at 10.4 %. This method of refinement caused only minor changes in the positions of the lighter atoms.

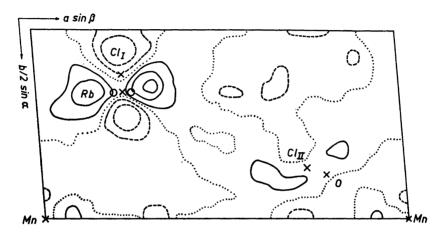

Fig. 1. Rb₂MnCl₄,2H₂O. Difference synthesis. Projection on (001) showing clover-leaf pattern obtained using hk0 data uncorrected for absorption. Contours are at intervals of 1 eÅ⁻²; negative contours are broken and zero contours dotted. The small crosses show the final atom locations. The small circles show the Rb-atoms of half weight each.

CRYSTAL DATA

The pertinent crystal data are given below:

Crystal system	$\mathrm{Cs_2MnCl_4,2H_2O}$: triclinic	$ m Rb_2MnCl_4, 2H_2O$ triclinic

The coordinates found, their standard deviations and the temperature factors are given in Table 2. The interatomic distances found are given in Table 3 and observed and calculated structure factors in Table 4. All crystallographic calculations (Lp-corrections, refinements, distances, and fouriers) were carried out on the computer GIER using Algol-programs written by Danielsen.⁵

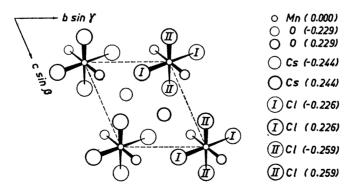

Fig. 2. Cs_2MnCl_4 , $2H_2O$. Projection along the a-axis. Figures in brackets indicate the x-values of the atomic parameters.

DISCUSSION

Each manganese atom is surrounded by four chlorine atoms and two water molecules forming discrete groups [MnCl₄,2H₂O]²⁻. The four chlorine atoms are situated almost exactly at the corners of a square. The water molecules, placed on opposite sides of the square, complete a trans-octahedral coordination (Fig. 2). The water molecule has two chlorine atoms as nearest negative neighbours at relatively short distances (3.17-3.29 Å). The angle Cl-O-Cl is 107° (Cs₂MnCl₄,2H₂O) and 105° (Rb₂MnCl₄,2H₂O). These facts suggest that hydrogen-bonds bind the octahedra together. The Cs(Rb)-atom is surrounded by eight chlorine atoms and four oxygen-atoms. The packing around the Cs(Rb)-atom may either be described as a distorted CsCl arrangement with eight Cl-atoms as neighbours, or as a close packing with twelve Cl and O-atoms as neighbours. The structure may be described as being of a distorted Cs₂PuCl₆-type (Zachariasen ⁸). The atomic radii of Pu⁴⁺ and Mn²⁺ are nearly equal, the Pu-Cl distance is 2.62 Å and the Mn-Cl distance found in Cs₂MnCl₄,2H₂O is 2.54 Å, and in Rb₂MnCl₄,2H₂O 2.54 Å and 2.58 A. The interatomic distances between Mn and Cl and between Mn and O are nearly the same as the corresponding distances in CsMnCl₃,2H₂O. In CsMnCl₃,2H₂O Mn—Cl is 2.50 Å and 2.57 Å and Mn—O is 2.08 Å. The main difference between the structures of CsMnCl₃,2H₂O and Cs₂MnCl₄,2H₂O is the cis-coordination of the water molecules in the former compound and the trans configuration of the latter. Established cis-trans isomerism is rather uncommon for kinetically labile coordination compounds.

The Cs-Cl distances 3.35 and 3.40 are shorter than the distance to be expected from the sum of Pauling's ionic radii (3.50 Å), but several other compounds containing Cs and Cl also have small Cs—Cl distances. In Cs₂CoCl₄ (Porai-Kochitz ¹⁰) the shortest Cs—Cl distance is 3.39 Å, in CsCuCl₃ (Wells ¹¹) the shortest distance is 3.40 Å, and in Cs₃Re₃Cl₁₂ Bertrand, Cotton and Dollase ¹² have found Cs-atoms in distances of 3.29 Å and 3.32 Å from Cl-atoms.

Acknowledgement. The author wishes to thank Mr. J. Danielsen, University of Århus, for valuable discussions and for the use of his Algol-programs for the computer GIER. The constant interest and encouragement of the head of this department, Professor P. Andersen, and of Professor S. E. Rasmussen, University of Arhus, are gratefully acknowledged. The Danish State Science Foundation has covered the cost of the Joyce-Loebl densitometer and of an X-ray tube.
