Interaction between Unlike Nonpolar Molecules:
Correction of the Geometric Mean Rule

Part 2. Dilute Systems

E. Sonnich Thomsen

The Royal Danish School of Pharmacy, Chemical Laboratory A, 2100 Copenhagen Ø, Denmark

Equations for correcting the geometric mean rule are established from published values of the attraction coefficients for dispersion forces and experimental correction factors for unlike critical temperatures. For the 131 systems examined (composed of noble gases, hydrogen, nitrogen, oxygen, carbon monoxide, normal and branched alkanes, cyclohexane, aromatic hydrocarbons, carbon tetrafluoride, and monochlorodifluoromethane) it is possible to account for the correction factors with almost the same precision as the original data used.

The preceding paper\(^1\) gave the basic formulae for correcting geometric mean rules for calculating interactions between unlike molecules from those between the like molecules involved. In this paper some more or less empirical correlations will be evaluated which enable us to calculate the geometric mean rule corrections for dilute (i.e. no correction for non-additivity of intermolecular forces is necessary) systems.

Numerical values of the attraction coefficients (\(k_{11}^o\), \(k_{22}^o\), and \(k_{12}^o\)) for dispersion forces are published by Dalgarno.\(^2\) The systems are the like and the 28 unlike binary combinations of the noble gases He→Xe, hydrogen, nitrogen, and methane. From these data the products \(f_1 \cdot f_2\) are obtained (Ref. 1, eqn. (3)).

Chueh and Prausnitz\(^3,4\) have compiled correction factors (which they call \(1-k\)) to the geometric means for critical temperatures. In this way experimental values of \(f_1 \cdot f_2 \cdot f_3 \cdot f_4 \cdot f_5 \cdot f_6\) (Ref. 1, eqn. (27)) are available for 68 non-polar and weakly polar systems composed of normal and branched alkanes (\(C_1\→C_8\)), cyclohexane, benzene, toluene, naphthalene, noble gases (He→Kr), hydrogen, nitrogen, oxygen, and tetrafluoromethane. Estimated and interpolated values are neglected together with systems involving ethylene, propylene, acetylene, carbon dioxide, and hydrogen sulphide, to ensure that dispersion forces alone are acting.

*Acta Chem. Scand. 25 (1971) No. 1*
The same unlike critical temperature correction factors (called $\beta$) are determined by Brewer for 35 systems composed of noble gases (Ne→Xe), hydrogen, nitrogen, carbon monoxide, methane, propane, and monochlorodifluoromethane (F-22). Here, too, carbon dioxide systems are disregarded.

The correction factor $f_\text{d}$

$f_\text{d}$ is defined in Ref. 1, eqn. (12); for $d_{12}$ is used the arithmetical mean of $d_{11}$ and $d_{22}$. These, in turn, are supposed to be proportional to the cube roots of the zero-point volumes, $v^o$.

The correction factors $f_\text{N}$ and $f_\text{c}$

In order to calculate $f_\text{d}$ (Ref. 1, eqn. (13)), values of the repulsive exponents ($v^o$) of the Lennard-Jones ($6-n$) potential functions are needed. Twenty-eight such values are taken from the tables 4−6 and 8−10 of Moelwyn-Hughes. (Carbon, metals, and hydrogen-bonded substances are neglected in establishing eqn. (1).) As $v^o > 6$, and as $v^o$ is assumed to increase with increasing molecular size, the data suggest

$$v^o = 6 + 0.145 \cdot v^o (\text{cm}^3/\text{mol})$$  \hspace{1cm} (1)

Even though this relationship (and/or the data used) needs more investigation (correlation coefficient = 0.639) it will be used temporarily for the present purpose.

For the ten systems common to Dalgarino, and to Chueh and Prausnitz, and the twenty-one systems common to Dalgarino, and to Brewer, $f_1$ and $f_\text{d}$ are eliminated, so that only $f_\text{N}$ and $f_\text{c}$ is left. It is seen from Ref. 1, eqns. (13), (24)−(26), and (28), that $n_{12}$ is the only unknown quantity. After solving these equations with respect to $n_{12}$, the following empirical relationship is established

$$n_{12} \cdot v = n_{12} - \frac{1}{2} (v_{11}^o + v_{22}^o) = A(I) \cdot A(n^o/I)/3$$  \hspace{1cm} (2)

(correlation coefficient = 0.957), where $I$ is the ionisation potential and, e.g., $A(n/I) = n_{11}^o/1-I_1-n_{22}^o/1_2$.

The correction factors $f_1$ and $f_\text{c}$

Now the products $f_1$ and $f_\text{c}$ are available, immediately for Dalgarino’s systems, but also for Chueh and Prausnitz’ and Brewer’s systems after eliminating $f_\text{N}$ and $f_\text{d}$.

From Ref. 1, eqns. (4) and (5), is seen that the unknown quantities are now the polarisability ($\chi_1$) of component 1 interacting with component 2, and the polarisability ($\chi_2$) of 2 interacting with 1.

Polarisabilities are related to refractive indices through the Lorentz-Lorenz equation, but to avoid defining molal volumes for a pair of isolated molecules, the zero-point volumes will be used and the resulting “refractive indices” denoted $\eta$. Thus for the pure substances

$$(\eta^2) = (2P + 1)/(1 - P); \quad P = (4\pi/3) \cdot N_0 \cdot v^o/\nu^o$$  \hspace{1cm} (3)

*Acta Chem. Scand. 25 (1971) No. 1*
Using the Lorentz-Lorenz equation simultaneously for \( \alpha_i \) and \( \alpha_i \) one has

\[
\alpha_i = \alpha_0 \left[ \frac{(\eta_i^2 - 1)}{(\eta_i^0)^2 - 1} \right] \frac{[\eta_i^0 + 2]}{[\eta_i^0 - 2]} \quad (i = 1, 2)
\]  

(4)

Macroscopic excess refractive indices are, to a first approximation and at least better than excess polarisabilities, parabolic and might be represented by \( x_1 \), \( \alpha_x \) constant, where \( x \) is the mole fraction. When the same approximation is used for \( \eta \), one has for \( x_1 = x_2 = \frac{1}{2} \) (as interactions between pairs of molecules are considered)

\[
\eta_1 = \eta_0 - y
\]

(5a)

\[
\eta_2 = \eta_0 - y
\]

(5b)

From the known values of \( f_i \), \( f_\alpha \), \( y \) was calculated for each of the 131 systems. It turns out that the following empirical relationship holds

\[
y = A(1/U) \cdot A(\eta \cdot U) \cdot [0.0563 - 0.0883 \cdot (|\Delta \chi|/(\chi_1 + \chi_2))]^{13}
\]

(6)

**Table 1.** The data for the pure substances.

| \( \chi \)   | \( x \) | \( \tau^0 \) (cm\(^2\)/mol) | \( \alpha^0 \times 10^{14} \) (cm\(^2\)/mol) | \( I \) (eV)

where $U = I \cdot \sqrt{x}$, and $x$ is the number of electrons in the outer shells. The correlation coefficient is 0.615, but as $y$ always appears together with $n$, eqn. (5), the precision of $\eta$ is about ±$1\%$.

**AGREEMENTS AND COMMENTS**

Using the data of Table 1, $f_1 \cdot f_\alpha$ are calculated for the Dalgarno systems, and $f_1 \cdot f_\alpha \cdot f_\delta \cdot f_\gamma \cdot f_c$ for Chueh and Prausnitz' and for Brewer's systems. The agreements are shown on Figs. 1 – 3.

* Ref. 2.  † Refs. 3−4.  ‡ Ref. 5.

The most serious disagreement occurs for He + H₂ ($f_1$ : Dalgarno: 0.94 and calc. = 1.15). The reason might be "quantum effects". This system is excluded from Fig. 1 and from the correlation coefficients.

The standard deviation for Dalgarno's systems is 2.9%. This is the same order of magnitude as claimed by Dalgarno.1 "With the possible exception of interactions involving Xe, in no case should the error exceed 10% and it is usually much smaller."

Chueh and Prausnitz report their data (converted to f) with two significant figures, e.g., f = 0.98, so that the precision is about ± 0.01. This is in agreement with the standard deviation found (0.018).

The standard deviation of Brewer's systems is 0.043, calculated from his data, compared to 0.080 for the theory presented here. The standard deviation of Brewer reflects, however, only his reproducibility and curve fitting. Systematic errors caused by solubility of Xe, F-22, and C₆H₆ in particular in the manometer oil are stressed by Brewer. When the systems involving one or more of these three gases are excluded, the standard deviations are in better agreement: 0.024 (Brewer) and 0.031 (this work).

On the whole it appears possible, with the theory presented here, to account for corrections to the geometric mean rule with almost the same precision as the original data.

To examine the possibility that one of the correction factors could in general be so close to one that it can be safely ignored, correlation coefficients were calculated with one of the correction factors removed in turn from the calculated f(total). It is seen from Table 2 that only f, can be ignored, but even in this case A(f) must not be too large. For Ne + CH₄, for example, A(f) = 8.6, f(total) = 0.72 (Chueh and Prausnitz), and = 0.70 (calc.), but f[total]/f = 0.65. In general, f = 1 increases approximately proportional to (|A(f)|)².
