

## Intermediary Phases in the $\text{Nb}_2\text{O}_5$ — $\text{MoO}_3$ and $\text{Ta}_2\text{O}_5$ — $\text{MoO}_3$ Systems

THOMMY EKSTRÖM

*Institute of Inorganic and Physical Chemistry, University of Stockholm,  
Box 6801, S-113 86 Stockholm, Sweden*

On specimens prepared within the temperature interval 640–900°C it was observed that intermediary phases  $\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$ ,  $7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$ , and  $6\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$  were formed in the  $\text{Nb}_2\text{O}_5$ — $\text{MoO}_3$  system, and  $\sim \text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$ ,  $6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$  in the  $\text{Ta}_2\text{O}_5$ — $\text{MoO}_3$  system. The phases have been characterized by their X-ray powder patterns, and unit cell dimensions for all, except  $\sim \text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$ , are given.

The  $\text{Nb}_2\text{O}_5$ — $\text{MoO}_3$  system has previously been investigated by Trunov *et al.*<sup>1</sup> For specimens prepared at 700°C, they reported the intermediary phases  $\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$ ,  $2\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$  and  $4\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$ . In specimens heat-treated at 1100°C, only  $4\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$  was found. More recently, Andersson<sup>2</sup> has reported two new phases  $\text{Mo}_3\text{Nb}_{14}\text{O}_{44}$  ( $7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$ ) and  $\text{MoNb}_{12}\text{O}_{33}$  ( $6\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$ ), formed by reaction of  $\text{MoO}_3$  vapour with solid H- $\text{Nb}_2\text{O}_5$ . In the  $\text{Ta}_2\text{O}_5$ — $\text{MoO}_3$  system, Kovba and Trunov<sup>3</sup> reported the presence of a phase  $4\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$ , and gave its unit cell parameters.

In this study, the  $\text{Nb}_2\text{O}_5$ — $\text{MoO}_3$  and  $\text{Ta}_2\text{O}_5$ — $\text{MoO}_3$  systems were investigated within the temperature interval 640–900°C, by heating appropriate amounts of  $\text{Nb}_2\text{O}_5$  (Kawecki 99.99 %) or  $\text{Ta}_2\text{O}_5$  (Koch-Light Lab. 99.9 %) with  $\text{MoO}_3$  (Mallinckrodt 99.5 %). After thorough mixing, the specimens were heated in sealed silica tubes at reduced pressure (1/4 atm. at room temperature) for periods usually ranging from 1–7 days. After the heat-treatment, the silica tubes were quenched in cold water. All the specimens were investigated by recording their X-ray powder patterns in a Guinier-Hägg focusing camera with  $\text{CuK}\alpha_1$  radiation, using potassium chloride ( $a = 6.29228 \text{ \AA}$  at 25°C) as an internal standard.

### The $\text{Nb}_2\text{O}_5$ — $\text{MoO}_3$ system

Series of samples  $(\text{Nb}_x\text{Mo}_{1-x})\text{O}_{3-0.5x}$  were prepared by heat-treatment at 640°, 750°, 800°, and 900°C ( $\pm 5^\circ\text{C}$ ). The 640°C specimens did not reach equilibrium after heat-treatment for one week, and regrinding and heat-

treatment for another week was necessary. The results of the X-ray powder phase analysis are given in Table 1. The intermediary phases  $\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$ ,  $7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$ , and  $6\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$  were thus observed irrespective of the temperature applied in the preparation of the specimens.

$\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$  ( $\text{Mo}_3\text{Nb}_2\text{O}_{14}$ ). Trunov *et al.*<sup>1</sup> reported this phase to have a tetragonal unit cell with  $a = 23.12 \pm 1 \text{ \AA}$ ,  $c = 3.995 \pm 5 \text{ \AA}$ . This is in concordance with the data obtained in the present study,  $a = 23.13 \pm 1 \text{ \AA}$ ,  $c = 4.000 \pm 2 \text{ \AA}$ .

A comparison with the powder pattern of  $\text{Mo}_5\text{O}_{14}$  showed that the two substances are isostructural. According to Kihlberg,<sup>4</sup> the crystal structure of  $\text{Mo}_5\text{O}_{14}$  is built up in a complicated way by  $\text{MoO}_6$  octahedra and  $\text{MoO}_7$  pentagonal bipyramids. The binary oxide seems to be metastable at its temperature of formation. Partial substitution of several transition metals, including niobium, for molybdenum has been found to have a stabilizing effect on the structure. Results of studies on this matter will shortly appear elsewhere.<sup>5</sup>

$7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$  ( $\text{Mo}_3\text{Nb}_{14}\text{O}_{44}$ ). This oxide is probably identical with the one reported by Trunov *et al.*<sup>1</sup> as  $2\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$ . They did not succeed to obtain this phase in pure state and gave the composition on the assumption that it was isostructural with a phase thought to be  $2\text{Nb}_2\text{O}_5 \cdot \text{WO}_3$ . The existence of this wolfram-niobium oxide has not been confirmed by later studies.<sup>6,7</sup> A comparison of the powder pattern obtained in the present study with the

Table 1. Experimental data for the system  $\text{Nb}_2\text{O}_5 - \text{MoO}_3$ , obtained from the X-ray diffraction patterns of specimens heat-treated at  $640^\circ$ ,  $750^\circ$ ,  $800^\circ$ , and  $900^\circ\text{C}$ . The brackets indicate traces of the phase concerned. The  $x$ -value corresponds to the formula

Composition $x =$	Observed phases
0.20	$\text{MoO}_3 + \text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$
0.35	$(\text{MoO}_3) + \text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$
0.40	$\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$
0.45	$\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3 + (7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3)$
0.50	$\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3 + 7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$
0.75	$(\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3) + 7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$
0.80	$7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$
0.85	$7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3 + (6\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3)$
0.89	$7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3 + 6\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$
0.92	$6\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$
0.95	$6\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3 + \text{Nb}_2\text{O}_5$

pattern for  $7\text{Nb}_2\text{O}_5 \cdot 3\text{WO}_3$  reported by Roth and Wadsley<sup>6</sup> shows that the two oxides are isostructural. The lattice parameters for the tetragonal niobium-molybdenum oxide are  $a = 21.024 \pm 5 \text{ \AA}$  and  $c = 3.818 \pm 2 \text{ \AA}$ . Kovba and Trunov<sup>8</sup> have reported " $2\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$ " to have the lattice parameters  $a = 21.01 \pm 1 \text{ \AA}$  and  $c = 3.816 \pm 2 \text{ \AA}$ . Recently, Andersson<sup>2</sup> has confirmed the existence of the  $7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$  phase, and reports that this phase decomposes at  $\sim 950^\circ\text{C}$ .

$6\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$  ( $\text{MoNb}_{12}\text{O}_{33}$ ). It was not possible, in this study, to obtain single phase samples at the composition  $4\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$  reported by Trunov *et al.*<sup>1</sup> (cf. Table 1 for  $x=0.89$ ) as an intermediary phase. At this composition, a phase was observed with higher niobium content together with the  $7\text{Nb}_2\text{O}_5 \cdot 3\text{MoO}_3$  oxide. The observed phase was not satisfactorily indexed by the lattice parameters for the  $4\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$  oxide given by Kóvba and Trunov.<sup>3</sup> Inspection of the powder patterns showed that the niobium-molybdenum oxide, obtained in this study, seems to be isostructural with  $6\text{Nb}_2\text{O}_5 \cdot \text{WO}_3$ .<sup>6</sup> The monoclinic unit cell has the lattice parameters  $a = 22.29 \pm 2 \text{ \AA}$ ,  $b = 3.823 \pm 2 \text{ \AA}$ ,  $c = 17.72 \pm 2 \text{ \AA}$ , and  $\beta = 123.4 \pm 1^\circ$ . Andersson<sup>2</sup> has reported the  $6\text{Nb}_2\text{O}_5 \cdot \text{MoO}_3$  oxide to be formed by reaction of MoO<sub>3</sub> vapour with solid H-Nb<sub>2</sub>O<sub>5</sub>.

### The Ta<sub>2</sub>O<sub>5</sub> - MoO<sub>3</sub> system

Series of samples  $(\text{Ta}_x\text{Mo}_{1-x})\text{O}_{3-0.5x}$  were prepared by heat-treatment at 640°, 750°, 775°, 800°, 850°, and 900°C ( $\pm 5^\circ$ ). The results of the phase analysis shows the intermediary phases  $\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$  and  $6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$  to form within the investigated temperature interval. At the lowest preparation temperature, 640°C, no intermediary phase was observed, and at 900°C, none of the two phases had decomposed. The results of the X-ray powder phase analysis at 850°C are given in Table 2.

Table 2. Experimental data for the system Ta<sub>2</sub>O<sub>5</sub>-MoO<sub>3</sub>, obtained from the X-ray diffraction patterns for the specimens heat-treated at 850°C. The brackets indicate traces of the phase concerned. The  $x$ -value corresponds to the formula  $(\text{Ta}_x\text{Mo}_{1-x})\text{O}_{3-0.5x}$ .

Composition $x =$	Observed phases
0.20	MoO <sub>3</sub> + $\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$ (melted)
0.35	MoO <sub>3</sub> + $\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$
0.40	$\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$
0.45	$\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$
0.50	$\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$ + $(6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3)$
0.80	$\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$ + $6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$
0.85	$(\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3)$ + $6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$
0.89	$6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$
0.92	$6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$
0.95	$6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$ + Ta <sub>2</sub> O <sub>5</sub>

$\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$  ( $\sim\text{Mo}_3\text{Ta}_2\text{O}_{14}$ ). Within the temperature interval 640–675°C, a phase with the approximate composition Ta<sub>2</sub>O<sub>5</sub>·3MoO<sub>3</sub> was beginning to form. In Table 3, the X-ray powder pattern for the  $\sim\text{Ta}_2\text{O}_5 \cdot 3\text{MoO}_3$  oxide is given. It has not been satisfactorily indexed, and single crystals of sufficient size for Weissenberg photographs have not been obtained.

$6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$  ( $\text{MoTa}_{12}\text{O}_{33}$ ). At about 810°C, the phase  $6\text{Ta}_2\text{O}_5 \cdot \text{MoO}_3$  was observed to form. A comparison with the powder patterns of  $6\text{Nb}_2\text{O}_5 \cdot \text{WO}_3$

Table 3. X-Ray powder diffraction data for  $\sim\text{Ta}_2\text{O}_5\cdot 3\text{MoO}_3$ .  $\text{CuK}\alpha_1$  radiation.

and  $6\text{Nb}_2\text{O}_5\cdot\text{MoO}_3$  showed that the three substances are isostructural. The monoclinic unit cell of  $6\text{Ta}_2\text{O}_5\cdot\text{MoO}_3$  has the lattice parameters  $a = 22.29 \pm 2 \text{ \AA}$ ,  $b = 3.821 \pm 2 \text{ \AA}$ ,  $c = 17.74 \pm 2 \text{ \AA}$ , and  $\beta = 123.4 \pm 1^\circ$ .

Kovba and Trunov<sup>3</sup> reported the presence of a phase  $4\text{Ta}_2\text{O}_5\cdot\text{MoO}_3$ . The lattice parameters of the monoclinic unit cell of  $4\text{Ta}_2\text{O}_5\cdot\text{MoO}_3$  was calculated with the assumption that this phase was isostructural with a phase thought to be  $4\text{Nb}_2\text{O}_5\cdot\text{MoO}_3$ . As mentioned above, the " $4\text{Nb}_2\text{O}_5\cdot\text{MoO}_3$ " phase seems to be the same as  $6\text{Nb}_2\text{O}_5\cdot\text{MoO}_3$ , observed in the present study. The results thus obtained for " $4\text{Ta}_2\text{O}_5\cdot\text{MoO}_3$ " is not in concordance with the data obtained for  $6\text{Ta}_2\text{O}_5\cdot\text{MoO}_3$  phase in the present study.

#### GENERAL REMARKS

The  $\text{Nb}_2\text{O}_5 - \text{MoO}_3$  system shows some similarities with the  $\text{Nb}_2\text{O}_5 - \text{WO}_3$  system, where the isostructural phases  $7\text{Nb}_2\text{O}_5\cdot 3\text{WO}_3$  and  $6\text{Nb}_2\text{O}_5\cdot\text{WO}_3$  have been reported by Roth and Wadsley<sup>6</sup> and Gruehn.<sup>7</sup> But the latter author suggested the  $6\text{Nb}_2\text{O}_5\cdot\text{WO}_3$  phase to have an extended homogeneity range to  $8\text{Nb}_2\text{O}_5\cdot\text{WO}_3$ . No extended homogeneity range has, in the present study, been observed for  $6\text{Nb}_2\text{O}_5\cdot\text{MoO}_3$ . The  $7\text{Nb}_2\text{O}_5\cdot 3\text{MoO}_3$  and  $6\text{Nb}_2\text{O}_5\cdot\text{MoO}_3$  oxides can be characterized as shear or block compounds.

No phase isostructural to  $\text{Nb}_2\text{O}_5\cdot 3\text{MoO}_3$  has been reported in the  $\text{Nb}_2\text{O}_5 - \text{WO}_3$  system. In the area  $\text{Nb}_2\text{O}_5\cdot\text{WO}_3 - \text{WO}_3$ , however, several phases exist,<sup>9,10,11</sup> which are related to the tetragonal potassium wolfram bronze type structure,<sup>12</sup> thus showing some similarities with the  $\text{Nb}_2\text{O}_5\cdot 3\text{MoO}_3$  phase

structure as having partially filled pentagonal tunnels with metal-oxygen running, parallel to the unique axes of the structures.

The phase relationships in the tantalum-rich area of the Ta<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub> system are rather complicated<sup>7,13</sup> and thus differs from the Ta<sub>2</sub>O<sub>5</sub>-MoO<sub>3</sub> system, where only 6Ta<sub>2</sub>O<sub>5</sub>·MoO<sub>3</sub> is observed. This phase is isostructural with the corresponding phases in the Nb<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub> and Nb<sub>2</sub>O<sub>5</sub>-MoO<sub>3</sub> systems and can thus be characterized as a shear or block compound.

The powder pattern for ~Ta<sub>2</sub>O<sub>5</sub>·3MoO<sub>3</sub> shows no similarities with any of the patterns observed in the Nb<sub>2</sub>O<sub>5</sub>-MoO<sub>3</sub>, Nb<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub> or Ta<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub> systems. But in the corresponding compositional area of the latter systems, there exist phases that in some respects are related to the tetragonal wolfram bronze structure.
