The Crystal Structure of Rubidium Triselenocyanate Hemihydrate

SVERRE HAUGE

Chemical Institute, University of Bergen, Bergen, Norway

The crystal structure of rubidium triselenocyanate hemihydrate, $\mathrm{Rb}(\mathrm{SeCN})_3\cdot \frac{1}{2}\mathrm{H}_2\mathrm{O}$, has been determined by X-ray methods, and refined by full-matrix least squares procedures. The crystals are orthorhombic, space group Fm2m (No. 42), with a=16.710(8) Å, b=4.833(3) Å, c=22.808(10) Å, and eight formula units per unit cell.

In the crystals, the triselenocyanate ions lie across crystallographic mirror planes. The three-selenium sequence of the triselenocyanate ion is nearly linear, with Se-Se-Se bond angle $176.9(3)^{\circ}$, and Se-Se bond lengths of 2.656(3) Å, which is 0.32 Å longer than single covalent selenium-selenium bonds.

Each of the selenocyanate groups is linear within the error. The terminal selenocyanate groups and the middle selenium atom, Se₂, lie nearly in the same plane. This plane makes an angle of 65.0° with a plane through the middle selenocyanate group and the terminal selenium atoms.

The triselenocyanate ion was first isolated by Verneuil ¹ in the form of the potassium salt. The crystal structure of the potassium salt, a hemihydrate, has been determined. Birckenback and Kellermann ³ prepared the cesium salt. Later, rubidium triselenocyanate hemihydrate, $Rb(SeCN)_3 \cdot \frac{1}{2}H_2O$, was isolated. Its crystal structure analysis, reported here, has been carried out as part of a study of linear three-selenium systems.

CRYSTAL DATA

Preparative and crystallographic data on rubidium triselenocyanate hemihydrate have been reported earlier.

The salt, $Rb(SeCN)_3 \cdot \frac{1}{2}H_2O$, forms long, brown, orthorhombic prisms elongated along the b axis, with a=16.710(8) Å, b=4.883(3) Å, and c=22.808(10) Å. The unit cell dimensions were determined from zero-layer Weissenberg photographs around the b and c axes, and evaluated by means of a least squares program.

There are eight formula units per unit cell; density, calc. 2.95, found 2.96 g/cm³. The space group, from systematic absences and subsequent structure

analysis, is Fm2m (No. 42).

Intensities were estimated visually from integrated Weissenberg photographs around the b and c axes, taken with $\mathrm{Cu}K\alpha$ radiation using the multifilm technique. The three-dimensional refinement was based on the h0l-h3l and hk0-hk1 data. 119 out of 132 h0l, 115 out of 117 h1l, 113 out of 120 h2l, 88 out of 93 h3l, 31 out of 32 hk0, and 23 out of 26 hkl reflections, in all 429 out of 455 independent h0l-h3l and hk0-hk1 reflections, accessible with $\mathrm{Cu}K\alpha$ radiation, were observed with measurable intensities. Three different crystals with approximately prism shape were used; the crystal used for the collection of the h0l data had cross-section 0.05×0.11 mm² and length 0.11 mm. The corresponding dimensions of the crystals used for the h1l-h3l and for the hk0-hkl data were 0.09×0.08 mm² and 0.125 mm, and 0.08×0.13 mm² and 0.08 mm, respectively. The linear absorption coefficient, $\mu=232$ cm⁻¹.

The intensities were corrected for absorption by the method of Coppens et al.⁵ A sub-division of 10, 4, and 14 Gaussian points along the a, b, and c

axes, respectively, were used for all three crystals.

The computer programs used for data reduction and absorption correction were made available by the Chemical Department of X-Ray Crystallography, Weizmann Institute of Science, Rehovoth, Israel, and modified for use on the IBM 360/50H computer by Dr. D. Rabinovich.

THE STRUCTURE ANALYSIS

With eight rubidium ions and eight triselenocyanate ions in the unit cell, and four water molecules, the space group Fm2m, if correct, would demand that the ions, and the water molecule, lie in special positions. The structure of the potassium salt, which has space group F2 and similar although monoclinic unit cell, indicated that in the rubidium salt, the triselenocyanate ion may lie across a mirror plane, with the middle selenocyanate group in the plane. This was confirmed through the structure analysis.

Approximate x and z coordinates of the rubidium ion and of the selenium atoms were found from the h0l Patterson map, by reference to the structure of $K(SeCN)_3 \cdot \frac{1}{2}H_2O$.² The carbon and nitrogen atoms were placed partly on the basis of subsequent h0l Fourier maps, and partly from the analogy with

the potassium salt.

The three-dimensional refinement was carried out on the IBM 360/50H computer, using a full-matrix least squares program with weighting scheme $1/(1+AF_{\rm o}+BF_{\rm o}^2)$. The values used for A and B were -1.2×10^{-2} and 6×10^{-5} , respectively. Refinement with isotropic temperature factors brought the reliability index, R, to 0.111. The observed structure factors were then corrected for secondary extinction by the method of Zachariasen,⁶ neglecting the absorption term, since this correction had been carried out earlier: $F_{\rm corr} = KF_{\rm o}(1+\beta CI_{\rm o})$, where $\beta = 2(1+\cos^42\theta)/(1+\cos^22\theta)^2$, and C was found to be 1.1×10^{-7} . The intensities of reflections that occurred more than once in the data set, were averaged, and such reflections thereafter included only once.

The final refinement, based on the corrected observed structure factors, and with anisotropic temperature factors for rubidium and selenium, brought the reliability index, R, down to 0.083, with unobserved reflections included if $|F_c|$ exceeds the observable limit.

The programs used for the least squares refinement, extinction correction, calculation of distances and angles, and least squares planes, were written

by K. Maartmann-Moe of this Institute.

The calculated structure factors were based on atomic scattering factors, given in the *International Tables* (Ref. 7, Table 3.3.1A). The scattering factors for selenium and rubidium were corrected for anomalous dispersion, real and imaginary parts (Ref. 7, Table 3.3.2A), by taking the amplitude of f as the corrected value.

The final atomic coordinates and temperature parameters are listed in Tables 1 and 2, and the structure factors in Table 3.

Table 1. Atomic coordinates for rubidium triselenocyanate hemihydrate, in fractions of orthorhombic cell edges, with origin on m2m. Isotropic temperature parameters (Å²) in the form $\exp-[B(\sin^2\theta/\lambda^2)]$. Standard deviations from least squares are given in parentheses.

THE TRISELENOCYANATE ION

Bond lengths and angles in the triselenocyanate ion, based on the atomic coordinates in Table 1, are listed in Table 4. The uncertainties in cell dimensions are taken into account in the given standard deviations. In Table 4, a prime denotes an atom located at (\bar{x},y,z) relative to the unprimed one; the primed atom is related to the unprimed one through the operation of the mirror plane parallel to (100) passing through the middle selenium atom, Se₂.

In the triselenocyanate ion, the Se-Se-Se angle is 176.9(3)°, and the three-selenium sequence is thus very nearly linear. The Se-Se bond length is 2.656(3) Å. In contrast to the present salt, where mirror plane symmetry makes the two Se-Se bonds equal, the three-selenium sequence in the corre-

Table 4. Dimensions of the triselenocyanate ion. Bond lengths (Å) and angles (°). Standard deviations are given in parentheses.

$Se_1 - Se_2 = 2.656(3)$	$\angle Se_1 - Se_2 - Se_1' = 176.9(3)$
$Se_1 - C_1 = 1.81(2)$	$\angle \text{Se}_1 - \text{C}_1 - \text{N}_1 = 178.4(17)$
$Se_2 - C_2 = 1.82(4)$	$\angle \text{Se}_2 - \text{C}_2 - \text{N}_2 = 179.3(30)$
$C_1 - N_1 = 1.17(3)$	$\angle Se_1 - Se_2 - C_2 = 88.58(15)$
$C_2 - N_2 = 1.16(5)$	$\angle \operatorname{Se}_{2} - \operatorname{Se}_{1} - \operatorname{C}_{1} = 95.3(8)$

sponding potassium salt ² is slightly unsymmetrical, with Se-Se-Se bond angle of 176.0° and Se-Se bond lengths of 2.689 and 2.648 Å. The total length of the three-selenium sequence (the sum of the lengths of the two bonds) is 5.337 Å in the potassium salt and 5.312 Å in the rubidium salt, the mean

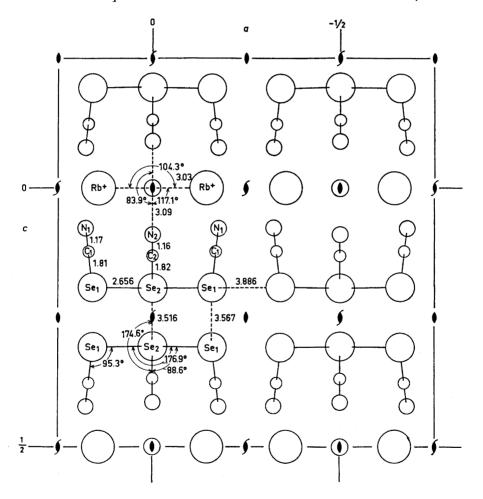

Fig. 1. Rubidium triselenocyanate hemihydrate as seen along the b crystal axis.

Acta Chem. Scand. 25 (1971) No. 8

value being 5.325 Å. The same mean total length is found for the very nearly linear, unsymmetrical three-selenium sequence in two salts of the triselenourea ion, the dichloride and dibromide.

Thus, from four structure analyses of linear three-selenium systems, one symmetrical and three unsymmetrical, it is found that the mean value of the Se-Se bond length is 2.66 Å. This is 0.32 Å longer than a single covalent selenium-selenium bond.⁹

The Se - Se - C bond angle at the middle selenium atom, Se_2 , is $88.58(15)^\circ$, and the Se - Se - C bond angle at the terminal selenium atom, Se_1 , is $95.3(8)^\circ$.

Each of the selenocyanate groups of the ion is linear within the error; the found values for the Se-C-N angles are 178.4(17)° and 179.3(30)°. The Se-C bonds are 1.81(2) and 1.82(4) Å, and the C-N bonds 1.17(3) and 1.16(3) Å. Within the accuracy of the analyses, these values are the same as found in the corresponding potassium salt,² and also for the selenocyanate ion in the crystals of potassium selenocyanate.¹⁰

The atoms of the terminal selenocyanate groups and the middle selenium atom, Se₂, are approximately co-planar, the largest deviation of an atom from a least squares plane being 0.05 Å (cf. Table 6). So are the atoms of the middle selenocyanate group and the terminal selenium atoms, Se₁ and Se₁', the largest deviation of an atom from a least squares plane being 0.02 Å. These two planes make an angle of 65.0° with each other.

Tables 5. Close interionic selenium-selenium contacts. Distances (Å) and angles (°). Standard deviations are given in parentheses.

Table 6. Distances from least squares planes. The equations of the planes were calculated with the selenium coordinates given six times the weight of the carbon and nitrogen coordinates, and refer to the axes of the unit cell, with coordinates Y and Z in Å.

INTERIONIC SELENIUM - SELENIUM CONTACTS

Each selenium atom in the three-selenium sequence has two close selenium – selenium contacts to atoms in adjacent triselenocyanate ions. The relevant data are listed in Table 5. In the table, a double-prime denotes an atom located at $(x,\frac{1}{2}+y,\frac{1}{2}-z)$ relative to the unprimed one, and a triple-prime denotes an atom located at $(x,y-\frac{1}{2},\frac{1}{2}-z)$ relative to the unprimed one; the double-primed and triple-primed atoms are both related to the unprimed ones through the operation of the mirror plane parallel to (100), passing through the middle selenium atom, Se₂, followed by the operation of the screw axis parallel to b near Se₂.

Table 5 shows close $Se_2 \cdots Se_2''$ and $Se_2 \cdots Se_2'''$ contacts of 3.516(4) Å, and $Se_1 \cdots Se_1''$ and $Se_1 \cdots Se_1'''$ contacts of 3.567(8) Å. For comparison, the Pauling ⁹

van der Waals radius of selenium is 2.00 Å.

The $\mathrm{Se_2}^{\prime\prime\prime}$ atom approaches the fourth coordination site of square-planar four-coordination at $\mathrm{Se_2}$. Thus, the $\mathrm{Se_1Se_2Se_1}^\prime$, $\mathrm{Se_2}^{\prime\prime\prime}$, and $\mathrm{C_2}$ atoms lie approximately in the same plane (cf. Table 6), the $\mathrm{Se_1}-\mathrm{Se_2}-\mathrm{Se_1}^\prime$ angle is 176.9°, the $\mathrm{Se_2}-\mathrm{C_2}$ bond bisects the $\mathrm{Se_1}-\mathrm{Se_2}-\mathrm{Se_1}^\prime$ angle, and the $\mathrm{C_2}-\mathrm{Se_2}\cdots\mathrm{Se_2}^{\prime\prime\prime}$ angle is 174.6°. The same structural feature occurs in the crystals of the potassium salt.²

The $Se_2 \cdots Se_2''$ contact, also 3.516 Å, occurs at a $C_2 - Se_2 \cdots Se_2''$ angle of 98.6°.

The two close contacts of the terminal selenium atoms occur at $C-Se\cdots Se$ angles of 164.9° and 108.8°.

THE ENVIRONMENT OF THE RUBIDIUM ION AND THE WATER MOLECULE

The water molecule lies in position of mm symmetry at (0,y,0). It is surrounded by two rubidium ions at distances of 3.03(3) Å and a Rb···O···Rb angle of $104.3(10)^{\circ}$, and by two N₂ nitrogen atoms at distances of 3.09(5) Å and a N···O···N angle of $83.9(11)^{\circ}$. The latter contacts probably involve weak O-H···H hydrogen bonds. The arrangement around the water molecule is approximately tetrahedral, the Rb···O···N angle being $117.2(6)^{\circ}$.

Table 7. Distances from the rubidium ion to neighbouring atoms. Standard deviation, 0.03 Å.

$Rb \cdots N_1(x,y,z) = 3.10 \text{ Å}$	$\mathbf{Rb} \cdots \mathbf{N}_{2}(x,y,z) = 3.23 \text{ Å}$
$Rb \cdots N_1(x, 1+y, z) = 3.00$	$\mathbf{Rb} \cdots \mathbf{N}_{\mathbf{z}}(x,y,\bar{z}) = 3.23$
$Rb \cdots N_1(x, y, \bar{z}) = 3.10$	$Rb \cdots O = 3.03$
$Rb \cdots N_1(x, 1+y, \bar{z}) = 3.00$	

The closest contacts of the rubidium ion are listed in Table 7 and shown in Fig. 2. The rubidium ion is surrounded by six nitrogen atoms at distances ranging from 3.00 to 3.23 Å, and by one oxygen atom, at 3.03 Å. Four of the six nitrogen atoms, at $Rb \cdots N = 3.00$ and 3.10 Å, lie exactly in a plane, parallel to (100), at x = 0.1768. The two remaining nitrogen atoms, at $Rb \cdots N = 3.23$ Å,

Acta Chem. Scand. 25 (1971) No. 8

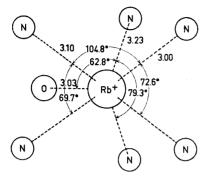

Fig. 2. The surroundings of the rubidium ion in rubidium triselenocyanate hemihydrate, as seen along the a crystal axis.

and the oxygen atom, lie in the plane (100) at x=0. The rubidium ion lies 0.54 Å from the former plane and 2.40 Å from the latter plane, between the planes. The Rb...O distance is in the normal range (cf. Ref. 6, p. 259), and so are the Rb...N distances, the sum of the Rb...N ionic radii being 3.19 A.9
