The Crystal and Molecular Structure of 2,5-Dihydroxy-1,4-benzoquinone at $-162^\circ$ C

DAG SEMMINGSSEN

Department of Chemistry, University of Oslo, Oslo 3, Norway

The crystal structure of 2,5-dihydroxy-1,4-benzoquinone has been determined at $-162^\circ$ C from three-dimensional counter data. The space-group is $C2/c$ with $a = 7.801(1)$, $b = 6.961(1)$, $c = 9.939(2)$ Å, and $\beta = 90.04^\circ$. Full matrix least-squares refinements have yielded a conventional $R$ value of 0.035 for 916 observations having $\sin \theta/\lambda > 0.55$. The molecules are situated at the centers of inversion, and there are two different C-O bonds [1.235(1) and 1.327(1) Å] and three different C-C bonds [1.506(1), 1.442(1) and 1.355(1) Å]. The planar structure shows some quinoid character although the double bonds are only partially localized. The hydrogen atom attached to the hydroxyl group appears to participate in two weak hydrogen bonds, one of which ties the molecules into infinite planar sheets, the other is a weak intramolecular interaction.

The crystal structure of the dipotassium salt of 2,5-dihydroxy-1,4-benzoquinone has recently been reported. The anion $C_6H_4O_4^{2-}$ was found to have $D_{3h}$ symmetry in the crystal within experimental error, thus there is virtually complete delocalization of the $\pi$ electrons along the 1-oxopropen-3-ol fragment. Intermediate character although not complete conjugation in corresponding bonds has also been found in the crystal structures of fluoro- and chloroanilic acids. To further investigate the effects of conjugation in this type of molecule, the crystal structure of 2,5-dihydroxybenzoquinone was determined. The determination was also carried out as part of a series of structure investigations of compounds containing the 1-oxo-propen-3-ol chain.

EXPERIMENTAL

The compound was synthesized by the method given by Jones and Shonle (Dec. 217 C), and suitable deep-red to orange crystals were grown by slow cooling of a solution of the compound in absolute alcohol. The crystals were frequently found to be twinned with (101) as the twin plane. Oscillation and Weissenberg photographs indicated monoclinic symmetry. $(a = 7.89$, $b = 6.95$, $c = 10.10$ Å, $\beta = 91.4^\circ$, $t = 25^\circ$ C). Systematic absence of reflections $hkl$ for $h + k = 2n + 1$ and $h0l$ with $l$ odd determined the space group to be either $C2$ or $C2/c$. The latter was assumed and proved to be correct by the structure refinements. Cell dimensions at $-162^\circ$ C were determined from the setting angles of 30 reflections with $2\theta$ values larger than 35°. Three-dimensional intensity data were collected from an almost rectangular crystal of dimensions $0.35 \times 0.45 \times 0.30$ mm on a SYNTTEX PI diffractometer with graphite monochromated MoK$\alpha$ radiation ($K_{\alpha 1} = 0.70926$ Å, $K_{\alpha 2} = 0.71354$ Å). The diffractometer was operated in the $\omega-2\theta$ scanning mode and equipped with an Enraf-Nonius liquid nitrogen cooling device (modified by H. Hope). The temperature at the position of the crystal was $-162 \pm 2^\circ$ C. Data were collected in one quadrant of reciprocal space to $2\theta_{\text{max}} = 80^\circ$ with a variable scan speed dependent on intensity. Below $2\theta = 50^\circ$ the scan speed was varied between 2 and 8° min$^{-1}$, above $2\theta = 50^\circ$ between 2 and 4° min$^{-1}$. In the latter shell a threshold value was applied to avoid measurement of very weak reflections ($<2\sigma(I)$). A symmetric scan range of 2° corrected for angular dependence of spectral dispersion were performed, the ratio of background to scan time was 0.6. A total of 1406 intensities excluding space group absences were measured, of which 1294 were greater than $2\sigma(I)$ and regarded as observed, the remaining 112 were rejected from the final structure analysis. The intensities and their standard deviations were corrected for Lorentz
Table 1. Fractional coordinates and thermal parameters with estimated standard deviations: A, for the refinement with an inner cut-off at \( \sin \theta/\lambda = 0.55 \) \( \text{Å}^{-1} \), B, for the refinement of all data. Expression for anisotropic vibration is \( -2\pi^2(ha\ast tU_{11} + \cdots + 2kb\ast c\ast U_{23}) \).

and polarization effects and a 2 % uncertainty to account for experimental uncertainties was included in the latter. Atomic form factors used were those of Doyle and Turner for oxygen and carbon atoms and those of Stewart et al. for hydrogen atoms.

Computer programs employed during the present study are those of Refs. 9 and 10.

CRYSTAL DATA (-162 °C)

2,5-Dihydroxy-1,4-benzoquinone, \( \text{C}_9\text{H}_6\text{O}_4 \), monoclinic. Space group \( \text{C}2\slash\text{c} \), \( a = 7.8008(14) \), \( b = 6.9405(13) \), \( c = 9.987(19) \), \( \beta = 90.044(10) \), \( V = 538.1 \) \( \text{Å}^3 \), \( M = 140.10 \) g mol\(^{-1} \), \( F_{(000)} = 288 \), \( Z = 4 \), \( D_{\text{calc}} = 1.729 \) g cm\(^{-3} \), \( D_{\text{calc}}(25 \) °C\) = 1.65 g cm\(^{-3} \).

SOLUTION AND REFINEMENTS

The structure was solved by direct methods and further refined by full matrix least squares methods. The function minimized was \( \Sigma w(F_0^2 - F_c^2)\), \( w = \sigma(F_0^2) \). The hydrogen atoms were located in a difference Fourier map at the end of the isotropic refinement. However, the hydrogen atom (H\(_O\)) attached to the hydroxylic oxygen was initially placed on the line joining the donor and acceptor of the intermolecular hydrogen bond. During the subsequent refinements the isotropic temperature factor of H\(_O\) increased from 3.0 to 5.5 \( \text{Å}^2 \), while the atom position shifted near to that determined from the difference map, whereupon the value of the thermal parameter again declined to 3.4 \( \text{Å}^2 \). Refinement with all data terminated with the residuals \( R = 0.038 \), \( R_w = 0.044 \) and \( S = 2.16 \). In the final refinements only data for which \( \sin \theta/\lambda > 0.55 \) were included, leaving 916 structure factors for a refinement of heavy atoms only. During these refinements the positional parameters shifted by up to 7 standard deviations, while all \( U_{ij} \) were reduced by amounts up to 4 standard deviations. The residuals obtained were \( R = 0.038 \), \( R_w = 0.030 \) and \( S = 1.2 \). Positional and thermal parameters from the refinement of "high" angle data are given in Table 1 together with the values from the refinement of all data.

In the following discussion heavy atom parameters from the high angle refinement will be considered, though only small changes in bond lengths (maximum 3 \( \times 10^{-2} \) \( \text{Å} \)) were observed.

An analysis of the molecular motion in terms of rigid body vibrations indicated that the molecule may be regarded as rigid since \( \Delta U_{\text{rms}} = 0.0003 \) \( \text{Å}^2 \). Corrections for librational motions range from 1 \( \times 10^{-3} \) (C1 - O1) to 4 \( \times 10^{-4} \) \( \text{Å} \) (C1 - C2) and have not been applied. The r.m.s. amplitudes range from 0.173 to 0.078 \( \text{Å} \) with the larger component perpendicular to the molecular plane (see Fig. 1). The structure factors can be obtained from the author upon request.

* Standard deviations of unit weight \( S = \Sigma w(F_0^2 - F_c^2)/(m - n) \).
2,5-Dihydroxy-1,4-benzoquinone

DESCRIPTION AND DISCUSSION

The molecular structure of 2,5-dihydroxy-1,4-benzoquinone in the crystalline state is shown in Fig. 1, which also shows the atom numbering scheme. The molecules are situated at crystallographic centers of inversion. Bond lengths and angles from both refinements are given in Table 2 together with hydrogen bond parameters.

The molecular structure of 2,5-dihydroxy-1,4-benzoquinone corresponds to that found previously in the chloro- and fluorooanilic acids. The structure is basically of quinoid character, however, some degree of conjugation exists along the sequence of atoms O1*—C1*—C3—C2—O2. Thus C1*—C3 [1.442(1) Å] is definitely shorter than C1—C2 [1.506(1) Å], indicating only minor conjugation across the latter bond. There is therefore markedly less conjugation in the 1-oxo-propan-3-ol chain than in the 1-oxo-propan-3-ol chain in the free acid and in the dipotassium salt. The C1—C2 bond in the present study is also probably shorter than the corresponding value in the salt [1.543(7) Å]. The bond lengths in the conjugated chain are similar to those found in the trans-enol arrangements of dimedone and phenylmalondialdehyde.

A slight tendency towards higher conjugation in the O1—C1—C3—C2—O2 skeleton upon substitution of hydrogen for the more electron withdrawing halogens may be noted. The C—O double bond increases from 1.215(3) Å in fluorooanic acid to 1.235(1) Å in the present work, while the C—O single bond decreases from 1.334(3) to 1.327(1) Å. Further the C—C double bond increases from 1.332(4) to 1.355(1) Å, while the C1—C3 single bond contracts from 1.456(3) to 1.442(1) Å. On the other hand the slight expansion of the C1—C2 bond from 1.496(4) to 1.506(1) Å may indicate a decrease in conjugation across this bond. The distances found in chloroanilic acid lie between those found for fluorooanic acid and the title compound except that the C—O single bond length does not differ significantly from that found in the present work.

The molecule is planar within the estimated standard deviations. The average absolute discrepancy from the root-mean-square plane through the heavy atoms in the asymmetric unit is only 0.001 Å, and the largest deviation (0.002 Å for C1) is not significant. The hydrogen atoms also lie in this plane with deviations for H_{C} and H_{O} of 0.035 and 0.026 Å, respectively.

A packing diagram of the structure is shown in Fig. 2. The molecules are linked together to form infinite sheets of hydrogen bonded layers [O...O, 2.728(1) Å] extending in the (101) plane. The stacking of layers perpendicular to (101) is such that C—O bonds of adjacent molecules overlap in an approximately antiparallel manner with an average layer separation of 3.16 Å. This suggests that the attractive

† Atoms marked with an asterisk are those centroymmetrically related within the molecule.
forces between layers may be partly due to
dipole-dipole interactions. The intermolecular
contacts between these atoms do, however,
correspond to normal van der Waals distances
(C1···O1, 3.06 Å; C2···O2; 3.09 Å). In addi-
tion to the O···O hydrogen bonds there are
other intermolecular interactions within
the sheets. These are from Hc to O1 and O2
of lengths 2.67 and 2.49 Å, respectively, and
are similar to CH···O contacts commonly
occurring in quinoid compounds.

The intermolecular hydrogen bond [O···O,
2.728(1) Å], is weak and of a similar length to
those found in fluoro- and chloroanilic acids
(2.720 and 2.769 Å, respectively). The hy-
drogen atom is displaced significantly off the
line joining the two oxygen atoms (ζO–H···O
= 114°) with an H···O separation of 2.12(2)
Å. An examination of intramolecular contacts
reveals that the H···O1 distance within the
molecule is only 2.23(2) Å, and although longer
than the intermolecular contact, it is shorter
than the sum of van der Waals radii for hy-
drogen (1.0 Å) and oxygen (1.4 Å), suggesting
the presence of a bifurcated hydrogen bond
arrangement. The corresponding intra-
molecular O···O distance is 2.658(1) Å and the
O–H···O angles ζ 114°. The intramole-
cular interaction constituting a five-membered ring
system is certainly weak, however somewhat
similar arrangements have previously been
found in the crystal structure of tropolone and
there is also evidence of such interaction in (–)
noradrenaline and some related compounds.
