Amineanionogold(III) Complexes. II. Calculation of Equilibrium Constants from Multiwavelength Spectrophotometric Measurements. Application to the Exchange of Bromide for Chloride in trans-Diaminedichloridogold(III) in Acidic Aqueous Solution

O. MØNSTED a and L. H. SKIBSTED b

a Chemistry Department I, Inorganic Chemistry, H.C. Ørsted Institute, University of Copenhagen, DK-2100 Copenhagen Ø, Denmark and b Chemistry Department, Royal Veterinary and Agricultural University, Thorvaldensvej 40, DK-1871 Copenhagen V, Denmark

Tetraamminegold(III) reacts with chloride in acidic solution to give a diaminedichloridogold(III) species which was isolated as a chloride salt. The diamminegold(III) species is tentatively assigned the trans configuration and the fast exchange of the two chloride ligands with bromide ligands has been investigated spectrophotometrically in 1.0 M perchlorate solution. At 25 °C the stepwise equilibrium constants are: $K_1 = 122 \pm 2$ and $K_2 = 29.9 \pm 0.5$ with $\Delta H_1 = -12.1 \pm 1.2$ and $\Delta H_2 = -13.5 \pm 0.7$ kJ mol$^{-1}$, respectively. General equations for processing multiwavelength spectrophotometric data to give stability constants and spectra for polynuclear and mixed ligand complexes are presented in an appendix.

Substitution of the first two ammonia ligands in the tetraamminegold(III) ion by bromide or chloride are rather fast processes which give diaminedihalogenido species with much more robust ammonia ligands.12 This suggests that the charge of the complex and/or the nature of the non-reacting ligands is important for the rate of such gold(III) substitution reactions and provides a strong incentive for measuring thermodynamic parameters which might provide a better background for a correlation between structure, stability and reactivity. The robustness of the diamminegold(III)-moiety ensures that the equilibrium constants for the halide exchange reactions at and around room temperature can be determined by standard spectrophotometric methods.

This simple system is well suited for a demonstration of the computational technique used to evaluate equilibrium constants and spectra from multiwavelength spectrophotometric data. The method has been used previously on other mononuclear systems3 but is equally applicable to systems involving polynuclear and mixed ligand complexes, for which generalized expressions are given in the Appendix.

EXPERIMENTAL

Materials. Potassium tetrachloridoaurate(III) from H. Drijfhout and Zoon’s, Amsterdam, was used as the starting material for the preparation of the gold compounds. Other chemicals were of analytical grade. Hydrobromic acid was distilled before dilution. Stock solutions of hydrobromic acid, hydrochloric acid, and perchloric acid were analyzed using standard methods.

Spectrophotometric measurements were performed on a Zeiss DMR 21 spectrophotometer with thermostatted cell holder and cell compartment.
Analysis. Analyses for C, N, H and Au (the latter gravimetric) were made by the Microanalytical Laboratory of the H.C. Ørsted Institute. Gold was also determined spectrophotometrically as described previously.\textsuperscript{1}

Preparations. [Au(NH₃)₄]NO₃\textsuperscript{5} and trans-[Au(NH₃)₂Br₂]Br\textsuperscript{1} were both prepared and purified as previously described.

trans-[Au(NH₃)₂Cl₂]Cl-H₂O trans-Diamminedichloridogold(III) chloride was synthesized by reacting 4.0 g, 8.9 mmol, of [Au(NH₃)₄]NO₃ in 40 ml of 4 M HCl at 45 °C for 20 min. The resulting yellow solution was filtered and mixed with 40 ml of saturated LiCl(aq) at room temperature. After cooling in ice the precipitate was filtered off, washed with 3 ml of ice-cold absolute ethanol and with ether. Yield 2.5 g. This crude product was dissolved in 10 ml of 0.01 M HClO₄ and recrystallized by slow addition of 5 ml of saturated LiCl(aq). After three such recrystallizations and drying in air at room temperature, the product appeared as a primrose-yellow microcrystalline powder. Yield 1.3 g of [Au(NH₃)₂Cl₂]Cl-H₂O, corresponding to 43%. Analysis Au, N, H, Cl. The absorption spectrum in the UV region in 0.10 M HCl+0.90 M HClO₄ showed no further changes after the second recrystallization: \(\lambda_{\text{max}}=277 \text{ nm}, \epsilon_{\text{max}}=1180 \text{ M}^{-1}\text{cm}^{-1}\), cf. Fig. 1. In 1.0 M HCl the absorption characteristics are 277 nm, 1300 M\(^{-1}\) cm\(^{-1}\). Drying the compound at 105 °C gave a loss in weight of less than 0.2 %.

The diaminenedichloridogold(III) ion exists as two geometrical isomers. Arguments for assigning the trans-configuration to the present complex are presented in the Results section.

Equilibrium measurements. Stock solutions of trans-[Au(NH₃)₂Cl₂]\textsuperscript{+} were freshly prepared by dissolution of weighed amounts of trans-[Au(NH₃)₂Cl₂]Cl-H₂O in 1.80 M HClO₄. By appropriate dilution with hydrobromic, hydrochloric, and perchloric acid, solutions with 0.100 M H(Br,Cl)+0.900 M HClO₄, 0.50 ≤ [Br] ≤ 0.100 M, were prepared and equilibrated at 0.9, 15.1, 25.0 and 30.2 °C, respectively. Absorption spectra were recorded between 260 and 360 nm, and data for 18 solutions at the selected wavelengths: 270, 277, 291, 304, 310, 328, 340 and 350 nm and at the four different temperatures were used to evaluate the data in Table 1.

CALCULATIONS

The calculations to give spectra and stability constants for the diamminebromidochlorido- and

dibromidogold(III) species are readily performed by nonlinear regression analysis by the generalized method described in the Appendix. The method was programmed in the Algol 6 dialect for the RC4000 computer of the H.C. Ørsted Institute.

With the 3 initial species, $\mu=3$:
1. Cl$^-$, 2. Br$^-$ and 3. [Au(NH$_3$)$_2$Cl$_2$]$^+$
and the 2 new species, $v=2$:
4. [Au(NH$_3$)$_2$BrCl]$^+$ and 5. [Au(NH$_3$)$_2$Br$_2$]$^+$,
the stoichiometric relations are given by the $C$ matrix as:

$$
C = \begin{bmatrix}
1 & 0 & 0 & -1 & -2 \\
0 & 1 & 0 & 1 & 2 \\
0 & 0 & 1 & 1 & 1
\end{bmatrix}
$$

In the nomenclature of the Appendix this matrix defines the stability constants as:

$$
[MBrCl]^+ = \beta_4[Cl^-][Br^-][MCl$_2^+$]
$$

and

$$
[MBr$_2^+$] = \beta_5[Cl^-][Br^-][MCl$_2^+$]
$$

with $M$=Au(NH$_3$)$_2^-$.. These constants are of course easily transformed into the consecutive constants, $K_1$ and $K_2$, by $K_1=\beta_4$ and $K_2=\beta_5/\beta_4$.

RESULTS AND DISCUSSION

Anation of [Au(NH$_3$)$_4$]$^{3+}$ by chloride in acidic aqueous solution where deprotonation and hydrolysis are suppressed$^3$ takes place in two kinetically separated steps, thereby allowing the isolation and purification of an intermediate product as a chloride salt. This product was identified as [Au(NH$_3$)$_2$Cl$_2$]Cl$^-$Hd220 from its elementary analysis. The UV-absorption spectrum of this salt dissolved in 0.020 M HBr+0.98 M HClO$_4$ had $\lambda_{max}=328.5$ nm and $\varepsilon_{max}=1155 M^{-1}cm^{-1}$, identical to that of trans-[Au(NH$_3$)$_2$Br$_2$]Br$^*$ dissolved in the same medium$^1$ and this is taken as an indication of the same configuration for the dichlorido complex.

Further anation has half-lives larger than 12 h for the ammonia/bromide ligand substitution under the experimental conditions for the present equilibrium measurements, and is therefore insignificant for freshly prepared solutions. The stepwise equilibrium constants for

trans-[Au(NH$_3$)$_2$Cl$_2$]$^+$ + Br$^-\rightleftharpoons$ $K_1$

trans-[Au(NH$_3$)$_2$BrCl]$^+$ + Br$^-\rightleftharpoons$ $K_2$

are presented in Fig. 2 and the calculated absorption spectra of the mixed bromido–chlorido and the dibromido complexes are given in Fig. 1.

The equilibrium constant for:

$$
[AuCl$_4$]$^- + 4Br^- \rightleftharpoons [AuBr$_4$]$^- + 4Cl$^-$
$$

has the value $\beta_4=10^{7.50}$ in aqueous solution$^6$ at 25 $^\circ$C and is relatively insensitive to ionic strength changes.$^8$ This value is comparable to the present finding of $\beta_2$, for the equilibrium between trans-[Au(NH$_3$)$_2$Cl$_2$]$^+$ and trans-[Au(NH$_3$)$_2$Br$_2$]$^+$, as ($\beta_2$)$^{14}=75$ and $\sqrt{\beta_2}=60$. The difference between the stability of bromido and chlorido complexes of Au(IIIII) is higher than for other square planar d$^8$ systems such as Pt(II) with ($\beta_4$)$^{33}=33^9$ and

$\footnote{The assignment of a trans configuration to the dibromido complex is based upon kinetic arguments assuming the kinetic $trans$ effect of coordinated bromide to be greater than that of coordinated ammonia. This $trans$ effect order is well documented for a number of transition metal ions, including square planar platinum(II), and would have to be the opposite for gold(III) if a cis configuration should be accounted for.}$

each other in the coordination sphere has little if any modulating effect on the acceptor properties of Au(III). In contrast to this, two cyanide ligands strongly increase the softness of Au(III), as judged from the value of $\sqrt{\beta_2}=750$ for the equilibrium: $^{12}$

$$\text{trans-}[\text{Au(CN)}_2\text{Cl}_2]^+ + 2\text{Br}^- \rightleftharpoons \text{trans-}[\text{Au(CN)}_2\text{Br}_2]^+ + 2\text{Cl}^-$$

and introduction of an amine ligand trans to the halides works in the opposite direction, as indicated by the value $K=15^{14}$ estimated for:

$$[\text{Au(dien)}\text{Cl}]^{2+} + \text{Br}^- \rightleftharpoons [\text{Au(dien)}\text{Br}]^{2+} + \text{Cl}^-$$

(dien=1,4,7-triazahexeptane).

The stepwise equilibrium constants for the exchange of bromide for chloride in $[\text{AuCl}_4]^{-}$, known from kinetic measurements, $^{4}$ are compared in Table 2 with the present findings for the trans-diamminegold(III)-moiety. There is no significant difference between the statistically corrected $^{13}$ constants and the affinity for exchange of a chloride with a bromide ligand at these Au(III) centres is thus independent of whether the cis-ligand is ammonia, chloride or bromide, or whether the trans-ligand is chloride or bromide. The observed high kinetic cis-effect $^{1,2}$ of ammonia relative to the two halides therefore has no thermodynamic counterpart.

The $\Delta H^\circ$ and $\Delta S^\circ$ values of Table 1 also confirm that the difference between the $K_1$ and $K_2$ values is statistically determined, since the $\Delta H^\circ$ values are identical within the estimated errors and the difference between the reaction entropies $\Delta S_1^\circ - \Delta S_2^\circ = 16 \pm 5 \text{ J mol}^{-1} \text{ K}^{-1}$ has the

![Graph showing temperature dependence of $K_1$ and $K_2$ for the trans-[Au(NH$_3$)$_2$Cl$_2$]$^+$ system in 0.10 M H(Cl,Br)+0.90 M HClO$_4$. Experimental data are given with a range corresponding to ± the estimated uncertainties and the solid curves computed from $ln K = (-\Delta H^\circ/T + \Delta S^\circ)/R$ are the basis for the parameters, $\Delta H^\circ$ and $\Delta S^\circ$.](image)

value expected from statistical arguments: \( R \ln 4 = 12 \text{ J mol}^{-1} \text{ K}^{-1} \). Solvation of chloride is stronger than that of bromide as indicated by the difference between the entropies of these ions dissolved in water \( S_{\text{Cl}^-} - S_{\text{Br}^-} = -26.1 \text{ J mol}^{-1} \text{ K}^{-1} \). For both reactions this difference in the solvational entropies gives a negative contribution to the overall reaction entropy and indicates that the difference between the solvation of the reactants and the products is the same for the two reactions or, in other words, the change in solvation of the complex is the same whether the first or the second chloride is exchanged with bromide.

**APPENDIX**

* Determination of stability constants from spectrophotometric data. The determination of stability constants is most effectively accomplished by using nonlinear regression analysis. This involves the assumption of an initial set of parameter values followed by an iterative refinement of these values. Assuming the validity of the Lambert-Beer law, the problem is linear in the molar absorptions coefficients and, therefore, initial values for only the stability constants are required in order to start the computations.

Stoichiometric relations of the form:

\[
\pi_i = \sum_{j=1}^{\mu} \gamma_{ij} \sigma_j \quad i = 1, 2, \ldots, \mu
\]

for \( \mu \) different species with total concentrations, \( \pi_i \), which interact to form \( \nu \) new species, may be combined with the relevant mass action equations:

\[
\sigma_i = \beta_i \prod_{j=1}^{\mu} \pi_j^{\gamma_{ij}} \quad i = 1, 2, \ldots, \mu + \nu
\]

with:

\[
\beta_i \equiv 1 \quad \sigma_i \equiv \pi_i \quad i = 1, 2, \ldots, \mu
\]

to give \( \mu \) nonlinear equations, in \( \pi_i \), for the calculation of the free concentrations, \( \sigma_i \), of all \( \mu + \nu \) species.

Eqn. (1) may in matrix notation collectively be written:

\[
t = C \pi \quad \text{(1a)}
\]

\[
t = (\pi_i), \quad C = (\gamma_{ij}), \quad s = (\sigma_j)
\]

and Newton's method for the iterative solution to:

\[
p_i = \pi_i \quad i = 1, 2, \ldots, \mu
\]

may be expressed as:

\[
p_{i+1} = p_i + \left[ C \frac{\partial e}{\partial p} \right]^{-1} [t - C s]
\]

with

\[
\frac{\partial \sigma_i}{\partial \pi_j} = \frac{\gamma_{ij} \sigma_i}{\pi_j}
\]

The starting approximation \( p_i = t \) is usually sufficient to assure convergence by eqn. (2), particularly when only moderately stable species are formed.

For \( \xi \) different solutions measured at \( \eta \) different wavelengths the experimental set of data at unit pathlength, \( \alpha_i \), may be expressed, using the Lambert-Beer law, as:

\[
\alpha_i = \sum_{k=1}^{\mu + \nu} \epsilon_k \sigma_k^j \quad \{i = 1, 2, \ldots, \eta \} \quad \{j = 1, 2, \ldots, \xi \}
\]

where the superscripts are used to denote different solutions. Derivatives of the general form \( \partial \alpha_i / \partial \epsilon_k \) and \( \partial \alpha_i / \partial \beta_\alpha \) are necessary for the regression analysis. Numerical differentiation for the evaluation of these quantities can be used, but when many parameters are present such methods tend to be somewhat uneconomical in computer time and are unnecessary for problems of the present type since analytical expressions for the differential quotients are easily derived. The first type is calculated directly from eqn. (3), and is:

\[
\frac{\partial \alpha_i}{\partial \epsilon_k} = \delta_{ik} \sigma_i^j \quad \delta_{ik} = \begin{cases} 1 & i = k \\ 0 & i \neq k \end{cases}
\]

To derive a formula for the remaining derivatives eqn. (3) may be written symbolically as:

\[
a = a(s(b, p(b)))
\]

with

\[
a = (\alpha_i), \quad b = (\beta_i), \quad p = (\pi_i), \quad \text{and} \quad s = (\sigma_i)
\]

which upon differentiation yields:

\[
\frac{\partial a}{\partial b} = \frac{\partial a}{\partial s} \left[ \frac{\partial s}{\partial b} + \frac{\partial s}{\partial p} \frac{\partial p}{\partial b} \right]
\]

Single elements in the matrices of this equation are given by:
\[
\frac{\partial q_i^j}{\partial \sigma_k^l} = \delta_{ij} \epsilon_{ik}^l
\]

\[
\frac{\partial \sigma_k^l}{\partial \beta_i} = \delta_{ki} \sigma_{\epsilon_i}^l \beta_i
\]

and by the solution of the set of simultaneous linear equations derived by differentiation of eqn. (1a):

\[
\frac{\partial p}{\partial \sigma} = \begin{bmatrix} C & \frac{\partial s}{\partial \sigma} \end{bmatrix}^{-1} \begin{bmatrix} C \frac{\partial s}{\partial \sigma} \end{bmatrix}
\]

Application of the methods just outlined gives equations involving \(\nu + \eta (\mu + \nu)\) parameters, which for even very simple systems may easily be so large a number that it will present difficulties when used without some modifications on a smaller computer.

If the parameter vector is defined as:

\[
q = \begin{bmatrix} \beta_i \\ \epsilon_k^j \\ \end{bmatrix}
\begin{cases}
\text{if} & i = \mu + 1, \mu + 2, \cdots, \mu + \nu \\
\text{if} & j = 1, 2, \cdots, \xi \\
\text{if} & k = 1, 2, \cdots, \mu + \nu
\end{cases}
\]

then the normal equations for the parameter value corrections, \(\Delta q\), can be expressed as:

\[
\left[ \begin{bmatrix} \frac{\partial a}{\partial q}^T \end{bmatrix} \begin{bmatrix} V(a) \end{bmatrix}^{-1} \begin{bmatrix} \frac{\partial a}{\partial q} \end{bmatrix} \right] \Delta q = -\left( \begin{bmatrix} \frac{\partial a}{\partial q} \end{bmatrix} \begin{bmatrix} V(a) \end{bmatrix}^{-1} \right) a_{\text{obs}} - a_{\text{calc}}
\]

or formally

\[
B\Delta q = c
\]

where \(V(a)\) is the usually diagonal matrix of variances upon the experimental data. This equation has a coefficient matrix, \(B\), with the lower right part in block diagonal form, i.e.:

\[
\begin{bmatrix}
B_{oo} & B_{o1} & B_{o2} & \cdots & B_{on} \\
B_{1o}^T & B_{11} & O & \cdots & O \\
B_{2o}^T & O & B_{22} & \cdots & O \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
B_{n\eta}^T & O & O & \cdots & B_{\eta\eta}
\end{bmatrix}
\begin{bmatrix}
\Delta q_o \\
\Delta q_1 \\
\Delta q_2 \\
\vdots \\
\Delta q_\eta
\end{bmatrix}
= \begin{bmatrix}
c_o \\
c_1 \\
c_2 \\
\vdots \\
c_\eta
\end{bmatrix}
\]

This special form allows a considerable reduction in the need for both computer time and storage, since it is readily verified that eqn. (5) is equivalent to

\[
\begin{bmatrix}
B_{oo} & \sum_{i=1}^\eta B_{oi}B_{i\eta}^T & B_{o1} \\
B_{1o} & O & B_{11} \\
B_{2o} & O & B_{22} \\
\vdots & \vdots & \vdots \\
B_{n\eta} & O & O \\
\end{bmatrix}
\begin{bmatrix}
\Delta q_o \\
\Delta q_1 \\
\Delta q_2 \\
\vdots \\
\Delta q_\eta
\end{bmatrix}
= \begin{bmatrix}
c_o - \sum_{i=1}^\eta B_{oi}B_{i\eta}^T c_i \\
c_1 \\
c_2 \\
\vdots \\
c_\eta
\end{bmatrix}
\]

The spectrophotometric problem is linear in all the \(\epsilon_k^j\) parameters. For a given set of stability constants these parameters may therefore be found directly by linear regression analysis from:

\[
B_{ii}e_i - c_i = -\begin{bmatrix} \frac{\partial a}{\partial e_i} \end{bmatrix}^T \begin{bmatrix} V(a) \end{bmatrix}^{-1} a_{\text{obs}}
\]

with

\[
\{ \epsilon_k^j \} = e_i
\]

and the matrix of partial derivatives given by eqn. (4).

Each iteration involving eqn. (5) is therefore most conveniently carried out by first finding suitable sets of \(\epsilon_k^j\) parameters from eqn. (7), and then with these parameters adjusting the assumed initial values for the \(\beta_i\) parameters by eqn. (6) in which now

\[
B_{ii}^T e_i = 0 \\
\quad i = 1, 2, \cdots, \eta
\]

which reduces the right-hand side to \(c_o\). This calculation, of course, also gives implicit adjustments to the \(\epsilon_k^j\) parameters. It therefore usually converges faster and gives more realistic error estimates than some alternative approaches in use which ignore off diagonal blocks in eqn. (5) and therefore only give conditional and sometimes unrealistically small variances upon the stability constants and spectral parameters.
