On the Extent of $p$-$\pi$-$\pi$ Conjugation in Some
$\beta$-Alkoxy-Substituted $\alpha,\beta$-Unsaturated Ketones

ESKO TASKINEN

Department of Chemistry and Biochemistry, University of Turku, SF-20500 Turku, Finland

The electric dipole moments of some title compounds in benzene solution have been
determined. By comparing the values of the experimental and estimated dipole moments it
was found that the mesomeric $p$-$\pi$-$\pi$ interaction in the $-\text{O} \equiv \text{C} \equiv \text{C} \equiv \text{O}$ moieties of these
compounds gives rise to mesomeric moments of $1.4-2.2$ D. This fact, in comparison with the
value of the mesomeric moment in simple alkyl vinyl ethers, shows that the carbonyl group of
the title compounds has a marked conjugation enhancing effect on the parent $-\text{O} \equiv \text{C} \equiv \text{C}$ system.

It was previously shown\(^1\) that in methyl vinyl ether the mesomeric $p$-$\pi$ interaction in the
vinylloxy moiety (1) leads to a mesomeric electric dipole moment ($\mu_m$) of $ca.$ 0.4 D,*

$$-\text{O} \equiv \text{C} \equiv \text{C} \leftrightarrow -\overset{+}{\text{O}} \equiv \text{C} \equiv \text{C}$$

(1)

directed from the positively charged oxygen atom towards the negatively charged $\beta$ carbon
of the vinyl group. The mesomeric moment is defined by eqn. (2) where $l$ stands for the
distance between the charged of $+q$ and $-q$ on the oxygen and $\beta$ carbon atoms,

$$\mu_m=q \cdot l$$

(2)

respectively. Since the value of $\mu_m$ is proportional to the distance between the charges,
higher $\mu_m$ values are likely to be encountered in compounds with longer conjugated systems
such as $\beta$-alkoxy-substituted $\alpha,\beta$-unsaturated ketones where the $p$-$\pi$-$\pi$ conjugation may be
described by (3).

$$-\text{O} \equiv \text{C} \equiv \text{C} \equiv \text{O} \leftrightarrow -\overset{+}{\text{O}} \equiv \text{C} \equiv \text{C} \equiv \text{O}$$

(3)

In compounds with the alkoxy group trans to the carbonyl group, the distance between
the opposite charges is about twice the corresponding distance in methyl vinyl ether. Since
the value of $\mu_m$ is also proportional to the magnitude of $q$ and hence to the extent
(“strength”) of conjugation, determination of $\mu_m$ values of these alkoxy-substituted

unsaturated ketones might give some information on the effect of the C=O group on the extent of conjugation in the vinyloxy group. In this work, attention is paid to the following compounds:

Dipole moment data for 2 and 3 were obtained from the literature; experimental work on 1 and 4 is reported here.

RESULTS AND DISCUSSION

The molecular structure of 1 appears to be suitable for an essentially unhindered $\pi-\pi$ conjugation: the MeO group is free to assume the energetically most favorable spatial orientation, i.e. the planar s-cis structure of methyl vinyl ether, and the two $\pi$-systems are likely to be coplanar (the ring carbons, excluding C-5, probably lie in the same plane; cf. the structure of 2-cyclohexen-1-one). The experimental $\mu$ value of 1, 3.74 D in benzene solution, is in satisfactory agreement with that for the corresponding 5,5-dimethyl derivative in CCl$_4$ solution (3.61 D). To evaluate the magnitude of $\mu_m$, the experimental $\mu$ value was compared with an estimated one, obtained by vector addition of the experimental dipole moments of appropriate, simple model compounds. Apparently, the approximate dipole moment of 1 may be considered to arise from a vector sum of the following dipole moments: (a) that of cyclohexanone (3.05 D, a mean of the values given in Ref. 6 for benzene solution), (b) that of dimethyl ether (1.35 D in benzene solution), (c) that of cyclohexene (0.33 D in the gas phase, the gas phase value being preferred because it is more accurately known than the solution value), and (d) the mesomeric moment $\mu_m$. The mesomeric moment was assumed to be directed from the ethereal oxygen towards the carbonyl oxygen. By increasing the magnitude of $\mu_m$ until the vector sum of the contributing moments (a)-(d) matched the experimental $\mu$ value one arrived at $\mu_m=2.2$ D.

![Diagram of molecules](image)

The magnitudes of $\mu_m$ in 2-4 were determined in a similar way. Because of molecular symmetry, the estimated dipole moment of 2 may be composed in a particularly simple way: the experimental dipole moment should be equal to a vector sum of the dipole moment of tetrahydrofuran-4-one ($\mu=1.720$ D in the gas phase) and the mesomeric moment. This requires $\mu_m$ to be ca. 2.0 D since the experimental $\mu$ value is 3.72 D in benzene solution. In a similar but assumingly less accurate way the dipole moment of 3 may be considered to arise from the following contributing moments: the dipole moments of tetrahydrofuran-4-one and cyclohexene (1.720 and 0.33 D, respectively), the induced moment due to the Me group (0.25 D) and the mesomeric moment $\mu_m$. The reported experimental $\mu$ value of 3.36 D in CCl$_4$ solution leads to a $\mu_m$ value of ca. 1.4 D for 3.

In 4 the bulkiness of the Me group cis to the MeO moiety forces the latter to assume a non-s-cis conformation. Previous studies on related molecules show\(^1\) that the trend towards a planar s-trans structure, where the conjugative interaction is most pronounced, is opposed by steric repulsions between the H atoms of the MeO group and the ring hydrogens a to the C=C bond. The high values of the mesomeric moment in I–3, however, suggest that despite these steric repulsions, a planar (or a nearly planar) s-trans structure might well be the most stable structure of 4, owing to the strong stabilizing effect of the \(p-\pi-\pi\) conjugation in this spatial orientation of the MeO group. The validity of this idea may be tested by determining the value of \(\mu_m\) in 4. Following the procedure outlined above for I–3, the estimated dipole moment of 4 may be compiled from the dipole moments of cyclohexanone, cyclohexene and dimethyl ether, together with the inductive moment of the Me group bound to the C=C bond and the mesomeric moment. From the experimental dipole moment of 4 (4.94 D) the mesomeric moment is evaluated to be about 1.7 D. This value, calculated for a planar s-trans structure, is a minimum value of \(\mu_m\); if the MeO group of the actual molecule is tilted out of the planar s-trans structure, the mesomeric moment must have a higher value to satisfy the experimental \(\mu\) value. However, it seems unlikely that the mesomeric moment would gain values higher than 1.7 D in any nonplanar structure of 4 in view of the \(\mu_m\) value of 2.2 D for I. The high value of the mesomeric moment in 4 is in agreement with its high thermodynamic stability, relative to the \(\beta,\gamma\) isomer.\(^1\)

It is interesting to note that the values of \(\mu_m\) derived above for I–4 (1.4–2.2 D) are roughly comparable with the magnitude of \(\mu_m\) (2.5 D) in a structurally related enaminoketone of the type 5.\(^2\) This shows that the abilities of an alkoxy group and an amino group to conjugate with an adjacent unsaturated system are essentially equal. In view of the considerable values of the mesomeric moment in these compounds it is clear that when compiling the estimated dipole moment from contributing moments, \(\mu_m\) can not be ignored (which occasionally has been the case\(^3\)) unless it can be shown that the conjugative interaction is negligible.

When comparing the relative magnitudes of \(\mu_m\) in I–4 it should be taken into account that the distances between the ethereal and carbonyl oxygens in 2 and 3 are about 13 % shorter than those in I and 4 (4.1 \(\times\) 10\(^{-10}\) m in 2 and 3, 4.7 \(\times\) 10\(^{-10}\) m in I and 4). To get an estimate of the relative extents of conjugative interaction in I–4, the \(\mu_m\) values of I and 4 should thus be decreased by 13 % to obtain \(\mu_m\) values comparable with those for 2 and 3. Thus the “corrected” \(\mu_m\) values for I and 4 are 1.9 and 1.5 D, respectively, to be compared with the actual \(\mu_m\) values of 2.0 and 1.4 D for 2 and 3, respectively. The relatively small range of these \(\mu_m\) values, 1.4 to 2.0 D, thus suggests that the extents of conjugative \(p-\pi-\pi\) interaction in all these compounds are approximately equal.

From the distance between the two O atoms of I one may thus calculate that in I the magnitude of \(|q|\) is ca. 0.10e\(^-\) (e\(^-\)=the charge of an electron). For comparison, in methyl

vinyl ether the values of $\mu_m$ (0.4 D) and the distance between the O atom and the $\beta$ carbon atom ($2.4 \cdot 10^{-10}$ m) lead to $|q|=0.04e^-$. Hence it may be inferred that the C=O group of $I$ has a marked conjugation-enhancing effect on the $-O-\cdot-C=C$ moiety.

**EXPERIMENTAL**

The preparation of $I$ and $4$ has been described previously. The dielectric constants were measured in benzene solution at 293.2 K. The $\mu$ values were calculated assuming $P_A=0.05 P_E$. For other details, see Ref. 9.
